11. Keep diesel fuel clean because one small particle of dirt can clog an injector, thus causing a delay which can lead to an accident.

C. How should one refuel a LP Gas Tractor?

1. LP Gas (Liquefied Petroleum Gas) is a liquid under pressure, if the pressure is removed it becomes a gas. Be sure all connections are securely tightened to prevent leaks.

2. Sometimes frost will form during the refueling process, if this happens be careful that you do not freeze your hand.

3. Never fill the LP gas tank full. (Follow safety instructions for your equipment.) The pressure will increase when the sun shines on the tank thus increasing the internal pressure. This could rupture the tank or a fuel line.

4. In case of fire shut off the fuel supply and allow it to burn out. Spray water on storage tank to prevent an increase in pressure.

5. Do not smoke around LP gas.

3. The liquid in a battery (A - will) (B - will not) be dangerous if spilled accidentally. _____

4. Removing a radiator cap suddenly from a pressure cooling system (A - is) (B - is not) dangerous. _____

5. A loose or broken spark plug wire (A - can) (B - cannot) cause a fire. _____

6. Operating a tractor engine with a low radiator temperature will result in (A - more power) (B - less power) than when the temperature is normal. _____

7. The use of proper clothing is an important part of safe machinery operation. T F

UNIT III

1. Operation of a modern tractor requires use of (A - both hands and both feet) (B - both hands and the left foot) (C - both hands, both feet and your head) (D - either hand and both feet). _____

2. A tractor with a wide front end is (A - more) (B - less) (C - no difference) likely to tip than a tricycle type tractor. _____

3. For better pulling up grades, weights should be added to (A - front wheels) (B - the rear wheels). _____

4. The oil pressure guage (A - will) (B - will not) tell you when you need to add a quart of oil. _____

5. A tractor speed indicator tells you (A - the number of revolutions per minute the engine is turning) (B - the number of feet per second the tractor is traveling). _____

6. If you are plowing and the red light comes on, indicating low oil pressure you should (A - leave the tractor engine running and go for help) (B - increase the throttle setting to see if the light will go out) (C - shut the engine off at once). _____

7. The ammeter or charge indicator light will show a discharge of the battery if (A - the generator is not charging properly) (B - there is a broken spark plug wire). _____

UNIT IV

1. Exhaust gases are deadly poisonous because they contain (A - carbon monoxide) (B - carbon dioxide) (C - hydrogen sulfide) (D - argon). _____

2. When cranking tractor, crank (A - should be spun to insure quick starting) (B - limited to quarter turns of crank) (C - limited to half turns of the crank). _____

3. Sparks in exhaust gases (A - are) (B - are not) a fire hazard. _____

4. When starting a tractor it is safe procedure to determine that gears (A - are) (B - are not) in neutral position. _____

5. It is (A - permitted) (B - not permitted) to operate a tractor in a closed building. _____

6. If you apply only one brake while traveling at a high rate of speed you will probably (A - kill the engine) (B - upset the tractor). _____

7. When you push down on a foot-pedal clutch, the transmission is (A - engaged) (B - disengaged). _____

8. The throttle on a gasoline tractor is actually a (A - governor control) (B - control attached to the carburetor) (C - device for increasing the fuel as it mixes with air). _____

9. It is important from a safety standpoint to have both brake pedals (A - adjusted for different pressures) (B - adjusted so pressure is applied evenly when the pedals are locked together). _____

10. It is a good idea always to (A - leave the ignition key in the tractor) (B - remove and place the ignition key where it is not available to children too young to operate the tractor). _____

11. The first step in starting any tractor is (A - turn on the ignition) (B - check the gearshift lever) (C - make certain the area is clear of other people). _____

12. If a tractor fails to start immediately (A - give up and do something else) (B - see if you can locate the trouble) (C - keep trying, because all tractors start if you crank them long enough). _____

UNIT V

1. A brake on each wheel assists in turning. When making a short turn apply the brake: (A - suddenly) (B - lightly) (C - gradually after reducing speed) (D - hard after reducing). _____

2. If you apply only one brake while traveling at a high rate of speed with no load you will probably (A - kill the engine) (B - upset the tractor) (C - skid sideways). _____

3. (A - all) (B - some) tractors can be shifted from one gear to another without using the clutch. _____

4. (A - one) (B - both) of the brakes should be used to make an emergency stop. _____

FARM MACHINERY SAFETY
...Tractor

I. Teaching Unit IX . . . Fork Lift and Loader Operation

II. Suggestions for Teaching:

A. Obtain pictures of fork lifts and loaders used commonly on farms in your area.

B. A model tractor with a loader could be used to demonstrate hazardous errors.

III. Objective:

To teach the student how to safely operate a fork lift or any similar device.

Iv. Motivation:

A. Using pictures of loaders and fork lifts, point out errors the operator might be making.

B. Demonstrate hazardous situations with model tractor and loader.

V. Central Problem:

A. What are some safety practices to use while operating a fork lift?

1. The manure loader is a common piece of equipment found on many Indiana farms. In many respects it is quite similar to the fork lift as far as safety is concerned. Some general safety rules are:

a) Keep the loader low to the ground while you are traveling. Be prepared to quickly lower the loader to the ground in case the brakes fail on an incline.

b) Do not overload the loader. This often results in tipping.

c) Many loads may shift in a turn or on a slope; therefore, when practicable the load should be secured to prevent rolling or sliding.

d) Loads suspended from the loader by a chain tend to swing sideways and often cause a serious tipping problem.

21492

D. What are some general refueling practices?

1. Keep an approved fire extinguisher on tractor and near the fuel tanks.

2. The following types of fire extinguishers can be used on fuel fires:

   a) Dry-chemical extinguisher

   b) Foam extinguisher

   c) Carbon dioxide extinguisher

3. Never use water to extinguish a gasoline or diesel fuel fire. These fuels will float on top of water and the fire will spread.

4. Sand or dirt can be used to smother the fuel fire.

5. To prevent static electricity from igniting the fuel keep a continuous contact of the hose nozzle and the fuel tank.

NOTE: See Farmer's Bulletin No. 2156 in Safety Notebook.

VII. Evaluation:

A. Does the student know how to preform the refueling process safely?

B. See questions on Unit X (Tractor).

VIII. References:

A. Farmer's Bulletin No. 2156, Pg. 3, 4, 6, 7, 8, 9, 10, 11, 12

B. Hazardous Occupations in Agriculture for 4-H Members, Pg. 38

C. Purdue Leaflet, S-49, Pg. 3

D. Purdue Leaflet, S-58

UNIT X

1. When refueling a tractor it is permissible to (A - have the motor running) (B - shut off the motor first) (C - either of the above). _____

2. It (A - is) (B - is not) permissible to refuel a hot engine. _____

3. A fire extinguisher of the (A - carbon tetrachloride type) (B - dry chemical or carbon dioxide type) should be mounted on the tractor. _____

4. If a diesel engine runs out of fuel (A - the fuel system has to be vented) (B - the engine can be restarted immediately). _____

5. (A - LPG) (B - Diesel) (C - Gasoline) tractors use a pressurized fuel tank. _____

6. It is the vapor of fuels that burns. These vapors, being lighter than air, float off when filling a gas tank and are not dangerous. T F

TESTING PROCEDURES

I. Practical Test

The student must demonstrate his ability to hitch, tow, back and unhitch a two-wheeled farm implement. He must demonstrate proficiency and observance of safety procedures that indicate, in the opinion of the instructor, that he is qualified to use this type of tractor for simple tasks. The driving must include turning and driving around obstacles. Gates, old tires, or a lime marker can be used to lay out a course. A side delivery rake provides a good test of driving skill. A suggested driving course and score sheet may be found in Appendix A.

The emphasis is on safety. Therefore this is not a "timed" event. The student must be allowed time to demonstrate his operating ability. There are at least 20 safety items (Appendix B) on which the student is to be graded during the practical test. It is suggested that five points be deducted for each item missed. A passing score would be 70 percent.

(Appendix A) Directions for Tractor Operators Test

1. Students will operate the tractor in a safe manner and at safe speeds at all times. Unsafe operation, at the discretion of the instructor, will disqualify a student. Road gear will not be used in negotiating the two wheel course layout. The use of steering wheel spinners is not permitted.

2. The two wheeled implement to be used will be determined by the local teacher. A two wheel trailer with a pin type hitch for quick coupling is recommended. A wooden frame can be mounted on the trailer if necessary to make it wider than the widest tractor be used.

3. Markers may be constructed according to the plans attached. Used golf balls may be obtained inexpensively by buying "practice balls" from any golf driving range.

4. Since the emphasis is upon safe operation this event is not timed. However, past experience indicates most students should be able to complete the two wheel course in six to eight minutes.

5. The severity of the two wheel course layout may be tailored to fit the ability of the students by changing the spacing between the markers. A marker spacing of the trailer width and six inches is a very severe course. A layout of trailer width and twenty-four inches may be necessary for younger boys. Boundary limits may also be increased to reduce the severity of the course.

6. Judging and Scoring

Two score sheets are kept on each student. One will be for driving safety, an example of which is given in Appendix B. The student will be scored on this sheet at all times he is operating a tractor, including the two wheel course layout.

N. Insist upon a sturdy, comfortable seat that can be adjusted. You must be able to reach all controls with ease at all times.

O. Put all controls in neutral before turning on the ignition key.

P. Excessive speed is dangerous and is also hard on machinery.

Q. Use special caution and slow speed when making turns or abnormal maneuvers, especially on slopes, near ditches, gullies, rough ground or fences.

R. Keep proper fire extinguishers on hand and ready for use. Check them at regular intervals and be sure that all operators know how to use them properly.

S. Before stopping equipment, place all controls in neutral, set the brakes, shut off the engine, place transmission in low or park, lower all hydraulic systems and remove the key. Removing the key will prevent children or unauthorized persons from moving or operating the equipment.

T. Never attempt to use a machine for something it is not designed for.

U. Observe all warnings, cautions, and safety precautions posted on the equipment or found in the operator's manual.

V. If possible do not operate machinery under diverse conditions.

W. When transporting machinery on roads or highways, use all safety warning devices required by law. (SMV emblems, flashing lights, etc.)

X. Avoid using heavily traveled roads. If it is not possible drive in the ditch or pull off the side of the road to allow traffic to pass.

Y. Installing a rear-view mirror will permit the operator to see when traffic is approaching from the rear.

Z. Wear rather close-fitting clothing. Loose clothing is more apt to get caught in moving parts. Tight fitting clothing may limit movement.

AA. Try to keep body temperature comfortable. A person who is extremely hot or cold is more apt to have an accident.

BB. Know first aid practices and carry a first aid kit on farm equipment.

CC. Think and practice safety at all times.

DD. Use caution when turning. Be sure that
not catch the equipment and flip it ove
operator.

EE. Many people have tripped and fallen int
stay far enough away to prevent this ty

VI. Evaluation:

A. Does the student know all safety practi
machinery operation?

B. See questions on Unit II (Machinery).

VII. References:

A. 4-H Tractor Program, Book 4, Unit 1, Pg

B. Purdue Leaflet S-48.

. 1-2.

FARM MACHINERY SAFETY

I. Teaching Unit III . . . Safety in Tillage Operations

II. Suggestions for Teaching:

A. Collect data on accidents involving tillage equipment.

B. Either have pictures of or actual tillage equipment used in your area on hand.

C. Think through specific hazardous of various pieces of tillage equipment used in your area.

III. Objective:

To teach the student how to use tillage machinery safely.

IV. Motivation:

A. Point out the dangers involved in the use of tillage equipment common to your area.

B. Give data on accidents involving tillage operations.

V. Central Problem:

A. How can tillage operations be done safely?

1. Never attempt to misuse tillage equipment.

2. Tillage equipment has sharp points so be careful when working with the equipment.

3. Always stay in the operators seat. Rough ground, hitting a rock, or a sudden movement can throw you off the tractor.

4. Keep adjustment levers placed so that no one can fall on them or be tripped by them.

5. Never attempt to adjust, unplug, or unclog tillage equipment while in motion unless the adjustment can be easily made from the operator's seat.

6. Never operate two pieces of tillage equipment on the same land. For example, a trailing tractor may run into stalled equipment.

7. Watch for hidden hazards such as rocks, holes, etc.

21515

The other will be the score sheet for the two wheel layout given below. This sheet may be used in several ways. The teacher will decide how it best fits his local conditions. The number of times an error is made is recorded. It is suggested if two or more marks are made for items 1 or 2 or three or more against items 3, 4, or 5 additional instruction is needed by the student.

The teacher may desire to determine a disqualifying score in terms of penalty points as indicated. Students exceeding this score would be considered as failing the test.

Two-wheel Course Test

I. Procedure

Two persons will be needed for recording scores, measuring, and observing operation.

The student will start and warm up tractor at starting line. Student signals instructor that he is ready to begin - engine running, brake set, in neutral. Instructor will give signal to begin.

Drive tractor to implement, stop tractor, dismount, and attach implement to tractor drawbar. Student will drive through course layout as shown in the diagram, returning implement to its starting point. Implement is unhitched, tractor returned to starting line and shut off.

II. Rules

A. No assistance will be allowed in hitching or unhitching. Implement will be on the ground.

B. Whenever dismounting from the tractor, at least one brake must be set. For tractors with automatic transmission, the selector lever must be in the "Park" or "Lock" position.

C. The test begins when the student mounts the tractor to start it. Test ends when the student has dismounted after shutting of the tractor.

D. The instructor may at his discretion require the student to change the direction of travel of his equipment when the trailer hitch gets in a cramped position, or when striking a marker, to prevent damage to the trailer or marker.

E. Stakes will be considered "knocked out of line" (See Item B of score sheet) when the stake is leaning so far that the golf ball will not stay on top when replaced without first straightening the stake. When scoring a stake "knocked out of line," the student will also be assessed a penalty for "golf balls dislodged" (Item A on score sheet).

III. Scoring

		No. of Times		Penalty Points
A.	Golf balls disloged	_____	x 50	_____
B.	Stakes knocked out of line	_____	x 100	_____
C.	Tractor engine			
	1. Stalled	_____	x 10	_____
	2. Grated gears	_____	x 10	_____
D.	Travel direction reversed to clear marker or prevent fouling of equipment	_____	x 10	_____
E.	Measurement in shed (no fractions)			
	1. Inches off center at front	_____	x 10	_____
	2. Inches off center at rear	_____	x 10	_____
	3. Inches or fractions thereof greater than one inch from rear of shed. Within one inch is perfect. Fractions to be counted as whole inch.	_____	x 10	_____
		Total penalty points		_____

Appendix B

The following safety procedure items are to be observed during the practical tractor proficiency test:

Starting Safety

1. Failure to check neutral or "park" position.
2. Failure to disengage clutch while starting engine.
3. Failure to check PTO for disengagement.

Driving Safety

1. Failure to engage clutch gently
2. Failure to ride on seat or stand on plateform in a safe manner
3. Skidding or pinning of rear wheels
4. Turning too short and fouling implement
5. Operation of tractor at unsafe speed

6. Moving tractor with brakes set

7. Inadequate precautions with people or objects in the way

8. Driving in such a manner as to be hazardous to equipment or surroundings

9. Any turn which causes inside rear wheel to leave the ground - automatic failure of test

Mounting and Dismounting Safety

1. Failure to check neutral or "park" position of gearshift

2. Failure to set brake or transmission in park before dismounting

3. Jumping on or off tractor

4. Failure to bring tractor to complete stop before dismounting

Other Safety

1. Smoking

2. Extra rider

3. Loose-fitting clothing

4. Others (list and explain)

FARM MACHINERY SAFETY

(R)

I. Teaching Unit I . . . Importance of Farm Machinery Safety

II. Suggestions for Teaching:

A. Collect data on farm machinery accidents.

B. Show pictures of farm machinery accidents.

III. Objective:

To create an awareness of the importance of farm machinery safety.

IV. Motivation:

A. About one out of every seven fatal accidents on the farm involve machinery excluding tractors. This ratio is even higher when non-fatal accidents are concerned.

B. Have students tell about farm machinery accidents or near accidents and the teacher should reinforce all points of safety.

V. Central Problem:

How important is farm machinery safety?

VI. Sub-Problems:

A. Is agriculture a hazardous occupation area?

B. What is the role of machinery in accidents?

C. How does the complexity of machinery affect accidents?

1. Many machines used in factories are more dangerous than farm machinery. However, farm machinery is operated under many different conditions. Also, the farmer does not operate the same machinery every day; therefore, he does not establish a routine and must renew his familiarity frequently.

2. Farm machinery is constantly changing. A new machine is different than the old one. The controls may be moved. Any minor change in a machine requires the operator to change his behavioral pattern if he is going to be a safe operator.

3. Farm machinery operators do not receive safety supervision to the extent that it is common in most industrial situations.

D. Why don't people follow safe human practices?

1. Human errors are responsible for most accidents. From 86-88 percent of all accidents are due to carelessness. People get in a hurry or are not thinking about their work. Being a safe operator is a matter of thinking about and avoiding hazardous situations.

2. During peak labor periods the machinery operator is in a hurry. He attempts to operate his machine in diverse conditions such as rain, mud, poorly lighted areas, dusty places, etc.

3. Modern farm machinery has many moving parts. While the operator is working on one part another part may catch his clothing.

4. Some farmers never attempt to learn safety practices for pieces of machinery. Some machines appear to be so simple that the operator thinks that there is no danger. All machines are dangerous if they are not used properly.

5. Some people simply believe that they are too smart to get involved in an accident.

VII. Evaluation:

A. Does the student understand the importance of farm machinery safety?

B. See questions on Unit I (Machinery).

VIII. References:

A. Purdue Leaflet S-48

B. 4-H Tractor Program, Book 4, Unit 1, Pg. 1

C. Hazardous Occupations in Agriculture for 4-H Members, Pg. 59.

FARM MACHINERY SAFETY

(R)

I. Teaching Unit II . . . Safety Practices Common to All Farm Machinery Operation

II. Suggestions for Teaching:

A. Make a poster, transparancy, or hand-out on safety practices common to all farms.

B. The teacher should supplement all of the following units with special instruction on the adjustments, care and operation for any given piece of equipment used in his area.

C. Ask victims of farm machinery accidents to talk to the class.

III. Objective:

To be certain that the student is familiar with basic safety practices common to most farms in the area.

IV. Motivation:

A. Show pictures of farm machinery accidents.

B. Give data connected with farm machinery accidents.

C. Most farm machinery is used only a few days each year. This is hardly enough time to become an expert operator. Since this is true the operator has a greater chance of misusing the machine thereby causing more accidents.

V. Central Problem:

What safety practices are common to all farm machinery accidents?

NOTE: The degree to which the following practices are repeated will probably depend upon how recently they have been discussed. Therefore, in some cases the basic principles will only need to be briefly reviewed when discussing such units as tilliage, seeding, etc. Emphasis would then be placed upon hazards particular to the specific equipment.

A. Permit only the operator on equipment. Never allow extra riders unless the machine is designed for them; an example would be a mechanical tomato picker or people riding on a wagon behind a baler.

B. While machinery is in operation, keep everyone away, especially small children.

C. Be certain that operators of all machinery are qualified - mentally and physically.

   1. Recognize limitations due to physical size and strength.

   2. Be sure that all operators have been properly trained for the machine they are operating.

D. Keep alert and avoid fatigue by taking frequent breaks. Get off the machine, walk around and drink or eat something.

E. Keep all shields and guards in place and in good repair. Never remove a guard or shield while the machine is running.

F. Keep your machinery adjusted properly and in good repair. Service according to the manufacturer's instructions. Read the operator's manual thoroughly before attempting to operate the equipment.

G. Disengage the power before attempting to make repairs, adjustments, or unclog the machinery.

H. Never attempt to jack up the equipment without using a jack stand to support the equipment. The jack stand will give the equipment greater stability and will support the equipment if the jack fails. Have someone else around before you crawl under the equipment.

I. Do not allow grease, oil, dirt, or mud to accumulate anywhere on the machinery where you may have to climb while getting on or off or while servicing the machine.

J. Keep the fuel system in good repair and use metal sediment bowls to reduce fire hazards.

K. Keep the exhaust system in good repair to reduce fire hazards and the possibility of carbon monoxide poisoning.

L. Use extreme care when working around moving parts.

M. Use caution while operating machinery that becomes weighted on one side, for example a combine that has a full grain storage hopper on one side.

8. Aways keep your tillage equipment properly adjusted and in good repair.

9. Never attempt to pull a load that is too heavy. This can cause tipping and slippage. Excess slippage can also cause an upset.

   a) The addition of weights can decrease slippage. If you add weights remember to balance the weight, front and rear.

   b) Using dual drive wheels can also decrease slippage. If you use duals remember your tractor is wider, so working near a fence or going through gates can be hazardous.

VI. Evaluation:

Does the student know how to operate tillage equipment safely?

VII. References:

References are quite numerous, therefore they are not listed.

FARM MACHINERY SAFETY

I. Teaching Unit IV . . . Seeding Equipment

II. Suggestions for Teaching:

A. Collect data on seeding accidents.

B. Have pictures of or actual seeding equipment on hand.

C. Using seeding equipment common in your area show or demonstrate hazards and safety precautions.

III. Objective:

To teach the student how to safely operate seeding equipment.

IV. Motivation:

A. Using picture or actual equipment point out hazardous practices or areas.

B. Have students tell about accidents involving seeding equipment.

V. Central Problem:

A. What are the hazards in using seeding equipment?

1. Keep your hands, arms and clothing away from moving parts.

2. Observe safe lifting practices. (Don't lift too much, use legs - not back, etc.)

3. Do not travel at high rates of speed.

4. Be sure to wash your hands after handling treated seeds, fertilizer, or chemicals.

5. Protect your eyes, keep both fertilizer and seed out of your eyes.

6. Keep all shields in place.

VI. Evaluation:

Does the student know the hazards of using seeding equipment?

VII. References:

References are quite numerous; therefore they are not listed.

2125

2126

2. There are two major types of sprayers and many variations of each type.

   a) Low pressure sprayer is used on most common farm crops.

   b) A high pressure sprayer is used on special crops such as tomatoes or fruit trees.

3. A chemical sprayer has five major parts:

   a) A pump to supply the pressure.

      1) Low pressure pumps are less expensive. They include gear pumps and nylon roller pumps.

      2) High pressure pumps work like a piston in an engine.

      3) Before storing your pump it should be flushed with water to remove all chemicals. Fill the pump with a light oil to prevent rusting and corrosion.

   b) The nozzle actually sprays the liquid onto the crop. There are many different types depending upon the pattern desired and the amount of chemicals to be sprayed.

      1) The most common nozzles work under low pressure (15 to 100 psi) and are located close to the crop. The three most common patterns are the hollow cone, the fan and the solid cone.

      2) High pressure nozzles usually spray a mist.

   c) The pressure regulator controls the spraying pressure. It is usually a screw device that simply restricts the amount of liquid being delivered to the spray nozzles. If a high spraying pressure is desired the line restriction is increased and if a low pressure is desired the opposite is true.

   d) The screens and filtering devices remove foreign material from the liquids. If the foreign materials reach the nozzles they can cause serious damage or malfunction. The pump can also be damaged.

      1) Never use dirty water to mix the chemicals. A rule of thumb is don't use water that is not clear enough to drink.

e) The supply tank holds the liquid mixture until it is needed.

1) Keep the tank clean.

2) Rinse thoroughly after use to remove the remaining chemicals.

3) Use special care when changing from one type of chemical to another. A reaction may take place thus neutralizing the new chemical or the residue from the new chemical may damage your crop.

4) A mixer or agitator should be in the supply tank to keep the chemical concentration equal in all parts of the tank.

B. What is a dry chemical applicator?

1. The most common dry chemical applicator looks very much like a fertilizer applicator.

a) Dry chemicals are usually either dust or granular.

b) Dry applicators are commonly found on corn planters. In most cases they apply the chemical in a band or row.

c) A gear meters out a given amount of chemical and it drops on the soil.

C. What should one remember when applying chemicals or using an applicator?

1. Never use a chemical before reading the label throughly. Follow all directions and observe all precautions and warnings.

2. Mix the chemical throughly and use only recommended amounts.

3. Calibrate your sprayer. Calibration depends on:

a) The ground speed of the applicator.

b) The area covered by each sprayer.

c) Rate of flow through each nozzle.

1) The rate of flow is dependent upon the spraying pressure and the size of hole in the nozzle.

2) The gallons per minute is equal to the application rate per acre, times the width in inches of the area sprayed per nozzle, times the ground speed divided by 5940.

NOTE TO TEACHER:

$$\text{gal per min} = \frac{\text{gal per A} \times \text{width of spray pattern} \times \text{mph}}{5940}$$

The figure 5940 provides a short cut because it takes into consideration several factors such as the number of square feet per acre, etc.

4. To change the application rate one can:

   a) Raise or lower the nozzle height

   b) Increase or decrease the spraying pressure

   c) Increase or decrease the number of nozzles

   d) Change the size of the nozzle

   e) Increase or decrease the ground speed

   f) Increase or decrease the chemical concentration

   g) Increase or decrease the pump speed

   NOTE: Carefully analyze the effects of these changes on the spray rate.

5. Never eat or smoke while using chemicals. This is an excellent method of consuming the chemical internally.

6. Always wash skin and clothing after handling chemicals. If any chemical is spilled on you, wash it off immediately. See the label to see if a further step should be taken, such as seeing a doctor.

7. Store chemicals in a safe place. Keep out of the reach of small children. Some chemicals should be kept in a locked metal cabinet.

8. Never mix chemicals near well or stream. A spill can cause contamination.

9. The original "Hazardous Occupations Order" for youth considered the certain chemicals a particular hazard and placed limitations on their use by persons under 16. The classification of chemicals may be changed from time to time; therefore, consult the current Hazardous Occupation Order for up-to-date information.

10. Never store chemicals in anything other than their original container. Bury or burn the container when it is empty.

VII. Evaluation:

Does the student know how to operate a chemical application properly and safely?

VIII. References:

A. 4-H Tractor Program, Book 4, Unit 4

B. See Purdue Leaflets, S-50, S-60, S-63, S-64

FARM MACHINERY SAFETY

I. Teaching Unit VI . . . Forage Equipment

II. Suggestions for Teaching:

A. Collect data on local forage equipment accidents.

B. Make a collection of pictures of forage equipment.

III. Objective:

To teach the student how to operate forage equipment safely.

IV. Motivation:

A. Do these statements sound familiar?

- 73 year old farmer killed when he fell in the path of a mower
- 37 year old falls into a silage chopper
- 24 year old killed when caught in a silage chopper
- 3 year old caught in silage chopper and killed
- silage chopper kills 42 year old farmer when his arm was caught in the conveyor

B. Using the pictures of forage equipment point out the dangerous areas of each machine.

V. Central Problem:

What is the safe way to use forage equipment?

VII. Sub-Problems:

A. Why is forage equipment dangerous?

1. Mowers, hay conditioners, choppers, balers, shredders and silo fillers are made to cut, crush or chop forage crops. Most forage equipment will do its job on anything that is run through it - including a person.

2. Some forage equipment such as choppers and silo fillers can easily pull you into their cutting parts. Use extreme caution when working with such equipment.

3. Cutting blades are sharp and must be kept sharp to insure proper cutting.

B. What precautions should one follow when using forage equipment?

1. Never walk in front of any forage equipment when it is running or being operated.

2. Keep all shields and guards in place.

3. When equipment is not in use keep all sharp points covered. Such as the front edge of a mower sickle.

4. Keep away from moving parts. Such as the conveyor on a silage blower or a baler intake.

5. Keep equipment in good repair and keep it adjusted properly. Consult your operator's manual for specifics.

6. It is a good practice to paint hazardous areas a contrasting bright color to warn people working around these areas.

7. Lawn mowers are also quite hazardous. Be careful of objects that might be thrown by the mower and keep feet and hands away from the cutting blades.

8. Never attempt to unclog any equipment while it is running. Shut it off and crank it by hand. Unclog the machine then engage the power.

VII. Evaluation:

A. Does the student know how to safely operate forage equipment?

B. See questions on Unit VI (Machinery).

VIII. References:

4-H Tractor Program, Book 4, Unit 5

2. Keep your equipment in good repair and keep it properly adjusted.

   a) Keep all clutches adjusted.

   b) Adjustments can save you money by harvesting more of your crop thus decreasing the field loss.

   c) Proper lubrication will decrease machinery wear.

3. If your havesting equipment becomes clogged, shut off all power. Attempt to unclog the machine by turning the power supply in a reverse direction with a wrench. Never attempt to unclog any machine while it is running.

4. Fire is a serious hazard during harvest time. If crops are dry, they will catch fire easily.

   a) Check the exhaust system and keep it in good repair.

   b) Do not refuel while engine is hot or running.

   c) Be careful not to over fill the tank or spill fuel.

   d) Do not start the engine immediately after refueling.

   e) Be sure matches, cigars, cigarettes and pipe ashes are cold before discarding them. If you smoke an ashtray would decrease the fire hazard.

   f) Carry a fire extinguisher on your harvesting equipment. Be sure it is in working order and know how to use it.

5. No rides should be allowed on machinery unless the machine is designed for riders.

VII. Evaluation:

A. Does the student know how to operate harvesting equipment used in his locality.

B. See questions on Unit VII (Machinery).

VIII. References:

A. FFA Safe Corn Harvesting Program Kit.

B. 4-H Tractor Program, Book 4, Unit 7.

For additional information on Harvesting Equipment see: Purdue Leaflets S-51, S-52, and S-53.

FARM MACHINERY SAFETY

I. Teaching Unit VIII . . . Wagons and Trailers

II. Suggestions for Teaching:

A. Collect pictures of wagons and trailers used in your area.

B. Collect data on any wagon or trailer accidents in your area.

III. Objective:

To teach the student how to operate wagons and trailers safely.

IV. Motivation:

A. A study conducted by Ohio State University showed that the number of accidents involving wagons was only second to tractor accidents.

B. Following are some examples of fatalities involving wagons:

17 year old - load shifted, wagon overturned crushing the victim

55 year old - fell off wagon when baler stopped and run over by loaded wagon

74 year old - run over by wagon while unhooking from corn picker.

12 year old - jumped off wagon and hit by passing auto

V. Central Problems:

A. What are the proper methods of operation or using wagons and trailers.

1. Keep your wagons and trailers in good repair:

a) Check the tires and be sure they are safe.

b) Be sure that the floor, sideboards and rack boards are in good repair:

1) Replace broken and weak boards.

FARM MACHINERY SAFETY

I. Teaching Unit VII . . . Harvesting Equipment

II. Suggestions for Teaching:

A. Obtain the film, "Hands Off." It can be obtained at Purdue University's A-V Center.

B. Collect data on local harvesting accidents.

C. Obtain pictures of harvesting equipment used in your area.

III. Objective:

To develop the ability to operate harvesting equipment safely.

IV. Motivation:

A. Showfilm, "Hands Off."

B. Post pictures of harvesting accidents.

C. Tell about local harvesting accidents and explain how they could have been avoided.

D. Point out hazardous areas of harvesting equipment.

V. Central Problem:

What is the proper way to operate harvesting equipment safely?

VI. Sub-Problem:

A. What are some types of harvesting equipment?

1. Combines, corn, vegetable and other specialized harvesters.

NOTE: All types of harvesting equipment used in your area should be covered in detail. Explain how it works and how it should be operated, include a safe means of unclogging.

B. What are some general safety precautions one should observe?

1. Keep all shields in good repair and in place. Shield as much of the equipment as possible without interfering with the harvesting process.

Foreword

This booklet, Leadership in Curriculum Development, is the child of experience. Like its predecessors, Reading in Grades 7-12 and Teaching Study Skills, it is the fruit of a relationship that has existed between Glassboro State College and the school districts which constitute the Curriculum Development Council for Southern New Jersey.

During the past three years the College and the member school districts have learned much about the excitement, the difficulties, the advances, and the problems which are involved in any sincere attempt to improve curricular programs. To that end, there is no royal road. There are not adequate directions for schools such as those in the Council, who want to join forces, consolidate resources, and pursue together the curricular values which can be achieved only when they are actively and consciously sought.

It has become increasingly apparent that the early stages are crucial in any curricular enterprise--when school or district needs are examined, when the study topic is selected, when leadership roles are determined, when faculty involvement is obtained, when board of education expectations are made realistic, when consultants are selected and oriented, and when a philosophy of curricular reconstruction is understood and accepted.

It is to guide districts, administrators, faculties, and consultants in the formative as well as the later stages of curricular projects that this Handbook was created. The ideas in it have obviously been distilled from the experiences of participants in the pioneering work which the Curriculum Development Council has conducted during the past several years of difficult but productive activity.

Council projects are built on the "do it ourselves" principle, undergirt by a conviction that only by participation, by agreement, and by experience, can schools and faculties change--and only as they change will the curriculum change.

It is believed that the materials in this Handbook, although designed for Curriculum Development Council members, will be equally pertinent and beneficial to any school district or group of districts actively attempting to improve curricula.

THOMAS E. ROBINSON
President
Glassboro State College

2127

FARM MACHINERY SAFETY

I. Teaching Unit X . . . Materials Handling Equipment

(This unit includes various types of conveyors, augers, distributors. etc.)

II. Suggestions for Teaching:

A. Collect pictures of materials handling equipment.

B. Collect data on materials handling equipment accidents for your area.

C. See Purdue Leaflet S-55 for a more complete list of materials handling equipment.

III. Objective:

To teach safe operation of augers, conveyors, portable elevators and related equipment.

IV. Motivation:

A. The following are some fatalities involving elevators, augers and conveyors:

- 44 year old pulled into silage feeder auger when loose clothing caught
- 12 year old - portable elevator fell on victim's head
- 14 year old - portable elevator fell on victim
- 66 year old - fell into elevator

B. Using pictures point out possible hazards of augers, conveyors, etc.

V. Central Problem:

A. What safety practices should one follow when using materials handling equipment?

1. Be sure that portable elevators are securly anchored to prevent them from falling.

2. When moving a portable elevator, lower it and move at a low rate of speed.

3. Be careful not to hit electrical power lines with the elevator. Numerous people have been electrocuted due to this careless act.

4. Keep all end shafts, belts, etc. shielded.

5. Never allow any one to ride up an elevator. Walking up one is also a dangerous practice.

6. All conveyors, augers, grinders, etc. should be shielded to the greatest extent practicable.

7. When working on conveyors, grinders, unloaders, augers, etc. that are controlled by automatic devices, be certain to shut off the device before starting to work on it. Use a fool-proof method to prevent another person from starting the device (use special locks, signs, etc.)

8. Be certain to dull sharp projections or place a shield on them to prevent someone from injuring themselves.

9. Place a flag, bright paint, etc. on equipment that is about head high, to prevent head injuries.

10. Place warning or caution signs around permanent equipment.

VI. Evaluation:

Does the student know how to operate materials handling equipment safely?

VII. References:

A. Purdue Leaflet S-55

B. Operator's Manuals for Specific Equipment.

14. When descending a sharp grade, equipment should be slowed by (a. braking) (b. keeping implement in gear). _____

15. The principal cause of accidents involving farm machinery is (a. faulty equipment) (b. operator error). _____

16. A long experienced farm machinery operator (a. does) (b. does not) have to be concerned about safety precautions. _____

17. When making turns near ditches, gullies or fences it is advisable to (a. speed up the machine to get away from the danger area as soon as possible) (b. slow down the machine to make the turn). _____

18. Before leaving the tractor seat for adjusting or repairing any equipment (a. shut off the tractor) (b. disengage the PTO) (c. shut off the tractor and disengage the PTO). _____

19. Adequate clothing (a. is) (b. is not) an important safety item for farm machinery operators. _____

20. In hot weather you should drink plenty of water and take extra salt (a. because you are thirsty) (b. to make up for perspiration losses). _____

21. (a. it is) (b. it is not) advisable to equip exhaust pipes from machinery engines with a non-spark screen to avoid fire. _____

22. Older machines that were manufactured without safety guards and shields (a. need them) (b. do not need them). _____

23. Power-take-offs are provided with shields to (a. protect them from dirt and dust) (b. protect the operator). _____

24. Small children (a. should) (b. should not) be permitted around farm machinery. _____

25. When performing the hitching operation you should (a. lift with your leg muscles) (b. lift with your back muscles). _____

26. When hand cranking farm equipment engines the crank should (a. be spun around to start the engine rapidly) (b. only be pulled up in quarter or half turns). _____

27. The crank handle should be held with fingers and thumb on (a. same side of crank handle) (b. thumb on opposite side of handle from fingers). _____

28. Engines should be cranked with the (a. equipment in gear) (b. equipment in neutral). _____

29. Keeping a machine in good condition and good adjustment makes it safer to operate. T F

30. Some machines may clean easier when operating. If this is known, it is all right to clean them without shutting off the power if you are careful. T F

31. One of the main reasons it is so easy to become entangled in a running machine when trying to clean it, is that you can't let go rapidly enough. T F

32. When stopping a machine at mealtime or at night, -it is not necessary to take the PTO out of gear as long as the clutch is disengaged when restarting. T F

UNIT III

UNIT IV

UNIT V

UNIT VI

1. When handling the cutter bar on farm machinery it is (a. permitted to leave tractor engine running) (b. necessary to shut off tractor motor). _____

2. When servicing or adjusting the hay baler it is (a. sufficient to disengage all power and shut off engine) (b. wait until baler flywheel has stopped rotating). _____

3. When working on the knives of a hay baler it is (a. permissible to move the flywheel) (b. not permissible to move the flywheel). _____

4. On forage harvesters it is (a. permitted) (b. not permitted) to open auger or cutterhead doors while cutterhead is operating. _____

5. A spring release is used on mowing machines to (a. allow cutter bar to swing back when striking an object) (b. allow mower to be thrown into gear without slipping) (c. brush trash off the cutter bar). _____

6. (a. it is advisable) (b. it is not advisable) to use a wood block to prevent the cutterhead of a forage harvester from turning when adjusting the knives. _____

7. Overloading a forage harvester will (a. get the job done faster) (b. cause the machine to clog). _____

8. After unclogging a hay baler, the operator should (a. stand close to the machinery to see that it will operate properly) (b. stand clear) (c. should be on the tractor seat) before putting it back in operation. _____

2) Drive or remove all protruding nails.

2. Use all safety warning devices while on public roads:

a) The state law requires you to properly display a SMV emblem while the wagon is on any public road.

b) Reflectors and tail lights help warn traffic approaching from the rear. You should have two tail lights or one light and two reflectors.

c) A red or amber flashing light should be displayed on the rear of your wagon or trailer if used at night.

d) Slow down and allow traffic to pass. Pull off the road if necessary.

d) If any of the safety warning devices required by law are not **fully visible on the tractor while pulling a** wagon or trailer they must be installed on the wagon. This includes the SMV emblem during the day or night, a flashing light at night, and tail lights.

3. Be sure your wagon or trailer is hitched properly:

a) Use safety pins.

b) Hitch only to the drawbar or recommended hitches, such as a hitch on the rear of a corn picker.

c) Self coupling hitches are available. These hitches prevent the hazard of a person between the wagon and tractor during the hitching process.

4. Use extreme care while pulling wagons and trailers:

a) Loaded wagons and trailers tend to push a tractor when you attempt to stop. Allow extra time to stop and stop gradually.

b) When pulling two or more wagons or trailers use extreme caution. The weight of the load is increased, this makes it more difficult to stop. A quick stop may cause the wagon to jack-knife or upset.

c) Decrease your speed. If a load shifts while traveling at high speeds an accident will occur.

d) If you are pulling an extremely heavy load you should have brakes on the wagon or trailer - especially at high speed.

e) Safety chains should be used as an extra precaution while pulling wagons or trailers on the highway.

5. Some wagons require special handling care:

a) Hoist wagon will very easily. Always unload both sides evenly to prevent an upset. Even when the hoist is lowered the wagon may not be as stable as a regular wagon.

1) Use break-away hydraulic couplers.

2) Never get under an elevated wagon bed.

b) Wagons that unload due to gravity upset easier because their center of gravity is elevated.

1) Never allow anyone in the wagon while it is unloading. There have been cases where persons have been trapped and suffociated in the grain.

c) Many self unloading wagons and trailers have conveyors or augers in them. These present special hazards.

1) Keep all moving parts shielded as much as possible.

2) The sides of the trailer or wagon slope. If a person slips, he may fall into the auger. Never get inside an auger wagon while it is unloading.

3) Manure spreaders have claimed many lives during the past decade. People fall into them and are killed by the rear unit.

4) Never attempt to unclog any self unloading device while it is running.

VI. Evaluation:

A. Does the student know how to operate a wagon or trailer safely?

B. See questions on Unit VIII (Machinery).

VII. Reference:

"How To Get Your Wagon Rolling Safely," 699.31-122, National Safety Council.

FARM MACHINERY SAFETY

I. Teaching Unit IX . . . Unhitching Equipment

II. Suggestions for Teaching:

A. Give examples of unhitching accidents.

B. Refer to film, "Hitching and Belting Pointers"

III. Objective:

To teach the safest methods for unhitching equipment.

IV. Motivation:

A. Give examples or tell how one could get hurt while unhitching.

B. Refer to Unit VI on Hitching.

V. Central Problem:

What is the proper procedure for unhitching equipment?

VI. Sub-Problem:

A. What are some precautions for unhitching?

1. Before unhitching equipment block the wheels so that the equipment cannot roll.

2. Securely support equipment that can fall easily.

3. Unhook all auxiliary equipment such as PTO shafts, hydraulic hoses, and controls that are attached to the tractor and equipment.

4. The last thing you do is the actual unhitching. Be sure the equipment will not drop, block the tongue to prevent this.

5. Pull the tractor away slowly making sure that the equipment is not still attached or rolling forward.

6. Be sure that you have placed the equipment so that it will not be a hazard to other vehicles, livestock or people.

7. Remember never attempt any portion of the unhitching procedure before the tractor has made a complete stop.

VII. Evaluation:

A. Does the student know how to unhitch equipment safely?

B. See auestions on Unit VI (Tractor).

VIII. References:

References are too scattered to mention.

21521

FARM MACHINERY SAFETY

(R)

I. Teaching Unit XI . . . Farm Equipment on Highways

II. Suggestions for Teaching:

A. Have on hand safety warning devices such as: SMV emblems, flashers, reflectors, flags, etc.

B. Have students tell of highway accidents involving slow-moving vehicles and analyze some of them.

C. Obtain a copy of Indiana's SMV emblem law from your local State Police Post or the Farm Safety Office, Agricultural Engineering Building, Purdue University.

III. Objective:

To teach the student how to operate farm equipment on the highway.

IV. Motivation:

A. When collisions involving farm equipment occur, the person on the farm equipment is the most likely to be killed or injured.

B. In Indiana about 300 reportable collisions occur each year between motor vehicles and slow-moving vehicles. The death rate is high in these accidents.

V. Central Problem:

What should one know about operating farm equipment on highways? See Unit VIII of Tractor Safety.

VI. Sub-Problems:

A. What safety warning devices should one use while operating farm equipment on highways?

1. SMV emblem - This emblem must be displayed any time a vehicle which ordinarly travels under 25 mph is on a public road or highway. This includes nearly all farm machinery. Many other states have similar laws.

a) The emblem must be fully visible from the rear; therefore, if you are pulling any equipment that blocks the view of the SMV emblem on the tractor, one must be displayed on the rear of the towed equipment.

2. A red or amber flashing light that is visible at least 500 feet to the rear must be displayed while any SMV is on a public highway or road at a time when visibility is poor, e.g. dark, fog, rain, etc. It should not be mounted over 8 feet high.

3. Other state regulations when visibility is poor include:

   a) Two white head ligts visible for a least 500 feet.

4. Other optional safety warning devices include:

   a) Red flags.

   b) Reflectors or reflecting tape to mark the outside edges of equipment.

   c) Clearance lights.

   d) An amber flashing light facing forward.

      NOTE: These safety warning devices are for your protection - use them.

5. Farm machinery may be moved on highways, they are exempt from size and weight restrictions if they do not damage the highway.

6. Any person driving farm machinery must have a driver's license unless he is traveling from field to field or farm to farm.

7. Any piece of farm machinery, including farm tractors, should have two red lights or one red light and two red reflectors visible 500 feet to the rear.

8. Any towed equipment should have a white or amber light on the equipment marking the farthest protection on the traffic side.

B. What rules of the road should an operator of farm equipment observe?

   1. Obey all laws pretaining to operating motor vehicles on public hgihways.

   2. Drive on the berm whenever possible.

   3. Yield to fast moving traffic.

   4. Allow traffic to pass you even if you must pull off the road and stop. (If three or more vehicles are following closely behind you are required by law to give them the right of way.)

ACKNOWLEDGMENTS

The Curriculum Development Council for Southern New Jersey owes its existence to Stanton B. Langworthy, Dean of Instruction at Glassboro State College, who promoted the idea of an area study council for southern New Jersey and advocated many of the procedures and practices which have been delineated in this Handbook. The organization is further indebted to Dr. Langworthy for reading the manuscript and contributing ideas and unpublished materials for inclusion in the booklet.

The Council is appreciative of the assistance given by the following in reading the advance copy and making valuable suggestions: Dr. Nila Banton Smith, Mrs. Elizabeth Bunce Daly, Mrs. Joan Krause, Dr. John L. Krause, Mrs. Jean Shaw, Dr. V. Eugene Vivian, Mr. Lawrence R. Winchell, Jr., and Mrs. Evelyn Winter.

The Council is most grateful also for the helpfulness of the following in preparing this Handbook: Dr. Truman Teed for the chapter heading drawings; Miss Helen Cioffi, Miss Carole Clipp, Miss Rita Derrickson, and Dr. Richard Zahn for important contributions; Mrs. Sylvia Brown for typing the manuscript; and President Thomas E. Robinson for reading the manuscript, making many suggestions, and making college facilities available for this work.

The Council recognizes the unique contribution of its member school districts and their local study chairmen whose recorded discussions on leadership problems formed the basis for many parts of this Handbook.

Finally, the organization is cognizant of the contribution of the following staff members of Glassboro State College who have served as consultants to Council member districts and tried out many of the practices advocated in this booklet:

Daniel A. Briggs, Ph. D., Professor of Education
Lawson J. Brown, Ed. D., Professor of Education
Karl O. Budmen, Ed. D., Professor of Education
Roy J. Butz, M. A., Assistant Professor of Education
Jessie S. Campbell, Ed. M., Assistant Professor II of Education
Stanley R. Cohen, Ed. D., Associate Professor of Education
John J. Collins, M. A., Assistant Professor of English
Marvin C. Creamer, M. S., Chairman, Department of Social Studies
Fred Detrick, M. A., Assistant Professor of Education
Elizabeth R. Duff, Ed. D., Professor of Education
Ruth Dyson, M. A., Assistant Professor II of Education
Anne L. Edwards, Ph. D., Associate Professor of Social Studies
George A. Hays, Ed. D., Professor of Education
Marion Hodes, M. S., Assistant Professor of Education
Ivar K. Jensen, Ed. D., Chairman, Department of Education
Horace T. Keller, Ed. D., Professor of Education
David D. T. Lloyd, M. A., Assistant Professor of English
Ida B. Morford, Ph. D., Professor of Education
Hazel F. Saindon, M. A., Associate Professor of Education, retired
Jean D. Shaw, M. A., Assistant Professor II of Education
Luther G. Shaw, Ed. D., Dean of Administration
Evelyn Slobodzian, M. S., Associate Professor of Education
Lawrence E. Smith, Ed. D., Associate Professor of Education
Nila B. Smith, Ph. D., Distinguished Service Professor of Education

Frank A. Wolfe, M. A., Assistant Professor of Education
Richard Zahn, Ed. D., Associate Professor of Education
Donald D. Zimmerman, M. A., Assistant Professor of Education

2128

5. Signal all movements. If your load blocks your rear vision, have someone follow you in another vehicle and have them signal stops and turns.

6. Never allow riders.

C. What special preparation should precede traveling on highways?

1. Be sure your equipment is in good repair. Check the tires, hitch, brakes, etc.

2. Be sure the brakes are locked together and equally adjusted.

3. Traveling at a slow rate of speed will decrease the chance of an upset or loss of control.

4. It is much safer for any trailing equipment to have its own braking system. (Some foreigh countries now require this.)

VII. Evaluation:

A. Does the student know how to operate farm equipment safely on public highways?

B. See questions on Unit XI (Machinery).

QUESTIONS FOR SAFE MACHINERY OPERATION

UNIT I

1. More than one-third of the accidents among the farm population involved farm machinery. T F

UNIT II

1. Before hooking up farm implements to tractor it is advisable to (a. shut off tractor power) (b. leave tractor motor running.) _____

2. When starting self-propelled farm machinery it is safe procedure to determine that gears (a. are) (b. are not) in a neutral position. _____

3. Extra riders are (a. always) (b. never) permitted on farm machinery. _____

4. Exhaust gases are deadly poisonous because they contain (a. carbon monoxide) (b. carbon dioxide). _____

5. When refueling farm machinery it is permissible to (a. have motor running) (b. shut off motor first). _____

6. A fire extinguisher of the (a. carbon tetrachloride type) (b. dry chemical or carbon dioxide type) should be mounted on the equipment. _____

7. If equipment is not provided with shields and guards over power shafts and drive mechanisms it is (a. all right to operate the machine) (b. not all right to operate the machine). _____

8. Farm machinery provided with the proper guards and shields is (a. completely safe) (b. never completely safe). _____

9. When operating machinery on rough, uneven ground (a. maintain normal speed) (b. reduce speed). _____

10. Belts or chains (a. may) (b. may not) be put on or removed while the pulley or gear is in motion. _____

11. To reduce tipping hazards rear wheels on equipment should be (a. as close together as possible) (b. as wide apart as possible). _____

12. To reduce fire hazard on farm machinery (a. metal sediment bowls) (b. glass sediment bowls) should be used on the engines. _____

13. All controls should be (a. in neutral) (b. in gear) before turning on the ignition key. _____

VT 013 310
Radar Speed Detection.

North Carolina State Board of Education, Raleigh.
MF AVAILABLE IN VT-ERIC SET.
PUB DATE - ND 5p.

DESCRIPTORS - *COURSE CONTENT; *RADAR; *TRAFFIC SAFETY; *TRAFFIC CONTROL; VOCATIONAL EDUCATION; INSTRUCTIONAL MATERIALS; SAFETY EDUCATION; TRAFFIC REGULATIONS; COOPERATIVE EDUCATION; *TEACHING GUIDES

ABSTRACT - This course outline details the minimum orientation and training requirements necessary to equip an uninformed officer in the use of radar. In general this orientation is to be conducted in two parts, the classroom instruction in the morning and the on-the-job training in the afternoon. Topics covered in the outline include: (1) Description of Instruments, (2) Range Setting, (3) Interpreting Meter Readings, (4) Enforcement Activity Records, and (5) Meeting Court Requirements. Also included is a series of questions that a defense attorney may raise in regard to the condition of the radar and the manner of its use. (Author/JS)

VT 013 310

9. PTO-driven forage choppers or balers do not always stop immediately after you have disengaged the power shaft. T F

10. On a mower, if possible, all lubricating and adjusting should be done from behind the cutter bar. T F

UNIT VII

1. It is (a. permitted) (b. not permitted) to unclog a corn harvester with a wooden stick. _____

2. Young people have quick reactions. It is (a. safe) (b. not safe) for them to unclog a corn picker harvester while the power is on. _____

3. The danger spots in a corn harvester are: (a. snapping rolls) (b. stalk ejectors) (c. husking rolls and snapping rolls) (d. chains, and elevators) (e. all of these). _____

UNIT VIII

1. It is (a. permitted) (b. not permitted) to get in a forage box wagon while it is operating. _____

2. When hitching wagons to a tractor for road operation (a. use a safety hitch pin and a safety chain) (b. use a safety hitch pin only) (c. use a safety chain only). _____

3. When hitching implements or farm wagons to a tractor you should (a. straddle the pole) (b. stand to one side of the pole). _____

UNIT IX

UNIT X

UNIT XI

1. When operating farm machinery on highway, vehicle should be provided with (a. lights and SMV emblem) (b. warning flags) (c. reflectors, lights, warning flags, and SMV emblem) (d. devices required by state law). _____

2. When collisions involving farm equipment and other vehicles occur the person on the farm equipment (a. is) (b. is not) most likely to be killed or injured. _____

3. Rear view mirrors (a. are) (b. are not) recommended for farm equipment moving on the highway.

TESTING PROCEDURES

I. Test of Operational Proficiency

The student must demonstrate his ability to safely operate those machines he expects to be using. This can be done on the home farm, land laboratory, school farm or other area satisfactory to the teacher and student. It can be done during the laboratory periods, field trips or supervised farm visits by the teacher. It must be demonstrated to the teacher and to his satisfaction. The student will pass the operational test given in Appendix A as a requirement to the successful completion of this program.

Vocational Agriculture Program in Safe Farm Machinery Operation

Farm Machinery Operation, Safety and Skill Test[1]

General Information

1. Successfully passing a FARM MACHINERY OPERATION, SAFETY, AND SKILL TEST is included as a part of the basic requirements for 14 and 15 year old youths to qualify for a Certificate of Exemption to the U.S. Department of Labor Orders Nos. 6, 7, 8, 9, and 10.

2. This test will involve three (3) separate phases or events:

   a. Starting with a tractor at a starting point, spot the tractor to a 3-point hitch implement, attach the implement to the tractor, move the tractor and implement approximately ten (10) feet, then detach the implement from the tractor, and return the tractor to the starting point.

   b. Starting with a tractor at a starting point, move the tractor to a self-unloading wagon, attach the wagon to the tractor drawbar, then properly connect the power-take-off shaft of the wagon to the tractor. Return to the tractor seat, engage the PTO and operate the unloading mechanism at low speed for approximately 30 seconds. Disengage the PTO, dismount and disconnect the PTO shaft from the tractor, return it to its proper transport position on the wagon, unhitch from the tractor drawbar, and move the tractor back to the starting point.

   c. Starting with a tractor at a starting point, spot the tractor to an implement equipped with a remote hydraulic cylinder, (with the implement in "transport" position). Connect the hydraulic hoses to the tractor, release the transport locking device (if present), operate the remote cylinder through one cycle, return the implement to transport position, engage the transport locking device, then disconnect hydraulic hoses, replace dust protective devices, and return the tractor to the starting point.

[1]Tests and score sheets developed by Robert G. White, Associate Professor of Agricultural Engineering, Michigan State University.

3. After the student has spotted the tractor to the implement, as outlined in Paragraph 2a, b, or c, and made the required connection between tractor and implement, he will then give the teacher the opportunity to check and approve the connection between tractor and implement before the implement is operated or moved in any way.

4. The student must work in a safe manner at all times. He must be on the tractor seat any time the tractor is in gear, any time the PTO drive is engaged, or any time the hydraulic controls are being operated.

5. Safe operating practices, including those set forth in the Safety Score Sheet, will be in effect at all times the student is actively involved in any of the phases of this test.

6. Certain unsafe acts, or failure to meet certain performance standards, will be considered as automatic failure to pass the test. They are:

   a. Putting the tractor in gear, engaging the clutch, engaging the PTO drive, or operating any of the hydraulic controls, without first being on the tractor seat.

   b. Fouling the tractor and any of the implements in any manner so as to damage the tractor or implements.

   c. Accumulating more than a total of one thousand (1,000) penalty points from the three events outlined above, including safety penalties.

   d. Any gross act of negligence or safety violation which, in the opinion of the teacher in charge, constitutes a major safety hazard to the student, teacher spectators, or equipment.

7. If a student fails to pass this test, but otherwise meets all the requirements for successfully completing this program, he may, at the discretion of the teacher in charge, be granted a second try. A second try, however, will be granted only after the student has had an opportunity for some additional study and coaching. Any student who fails this test for a second time, will not be given another opportunity during the current calendar year.

Scoring Procedures

1. Scoring will be done on a "points off" or "points penalty" basis, and will cover both safety and operational skills as outlined on the attached score sheets.

2. Teachers may, at their discretion, require an applicant to stop or change the direction of travel or change his procedural methods, if, in their opinion, damage may occur to equipment or injury occur to a person.

Farm Machinery Operation Safety Score Sheet

_____
Student's Name

Procedure:

Each student will be scored on safety any time he is concerned with tractor or machinery operation. This includes practice, as well as before, during and after the machinery tests. Safety officials will be on hand to record violations during these periods.

Scoring:

	No. of Times Found	Points Added
Starting Safety		
1. Failure to check neutral position	____ x 100	____
2. Failure to disengage clutch while starting engine	____ x 10	____
3. Failure to check disengaged position of PTO	____ x 50	____
Driving Safety		
1. Failure to engage clutch gently.	____ x 10	____
2. Failure to ride on seat or stand safely on platform.	____ x 100	____
3. Skidding or spinning wheels when starting	____ x 50	____
4. Turning too short and fouling implement.	____ x 20	____
5. Operation of tractor at unsafe speed.	____ x 100	____
6. Moving tractor with brake set.	____ x 10	____
7. Inadequate precautions when teachers, other students, or spectators, get in the way.	____ x 100	____
8. Any turn which causes inside rear wheel of tractor to leave ground.	Disqualifies Applicant	
Mounting and Dismounting Safety		
1. Failure to set brake before dismounting.	____ x 50	____
2. Failure to dismount to insert or remove drawbar pin.	____ x 20	____
3. Failure to bring tractor to complete stop before dismounting.	____ x 100	____
4. Failure to mount and dismount safely.	____ x 50	____
Other Safety		
1. Smoking	____ x 20	____
2. Extra riders	____ x 100	____
3. Loose fitting clothing	____ x 50	____
4. Failure to give teacher an opportunity to check the completeness of the connection between tractor and implement.	____ x 100	____
5. Failure to release and reset any transport locking device under Paragraph 2c.	____ x 100	____
6. Failure to operate equipment as called for in Paragraph 2a, b, and c of the instructions in a safe manner.	x 50	

Farm Machinery Operation Score Sheet

_____
Student's Name

Procedure:

Two officials will be available for timing, recording scores, and observing operation.

The student will start and warm up the tractor at a designated starting point. He will then move the tractor to the implement, perform the required operations, and then return the tractor to the starting point. Time will not be recorded, but officials may set an arbitrary time limit on an event if the applicant appears to be taking an unreasonably long time to finish the event.

Rules:

1. No assistance will be allowed in any of the hitching or connecting operations.*
2. Whenever dismounting from tractor, at least one brake must be set. For tractors with automatic transmissions, the selector lever must be in the "Park" or "Lock" positions.
3. Remember, officials must be given an opportunity to check the completeness and safeness of attaching the tractor to the implement as outlined in 2a, b, and c of the instructions prior to his activating, moving or operating the implement.

	No. of Times	Points Added
a. Three-Point Hitch		
1. Tractor engine stalled.	____ x 10	____
2. Gears grated.	____ x 10	____
3. Additional attempts at spotting tractor.	____ x 10	____
4. Failure to use crank on lift arm (if needed to equalize lift arms to implement).	____ x 50	____
5. Failure to lift implement from ground before moving it to new location	____ x 100	____
6. Failure to lower implement gently.	____ x 50	____
b. Power-Take-Off		
1. Tractor engine stalled.	____ x 10	____
2. Gears grated.	____ x 10	____
3. Additional attempts at spotting tractor.	____ x 10	____
4. Failure to first attach implement to tractor drawbar.	____ x 50	____
5. Failure to physically check to see that all shielding is properly attached, or that self-contained shield is free to rotate on PTO shaft.	____ x 100	____
6. Failure to gently engage PTO power to implement.	____ x 50	____

*Officials should be sure that PTO splines are clean and free of paint, 3-point hitch equipment is in good condition, and hydraulic hose break-away

c. Remote Hydraulic Cylinder

1.	Tractor engine stalled.	_____ x 10	_____
2.	Gears grated.	_____ x 10	_____
3.	Additional attempts at spotting tractor.	_____ x 10	_____
4.	Failure to place remote hydraulic control lever in neutral or non-pressure position before making or breaking connection.	_____ x 50	_____
5.	Failure to wipe couplings or coupling covers clean before putting them in place.	_____ x 100	_____
6.	Failure to cycle remote cylinder gently.	_____ x 50	_____

Total Machinery Points Penalty	_____

Course Description

INTRODUCTION TO LAW ENFORCEMENT

T-PSC 101

A general course designed to familiarize the student with a philosophy and history of law enforcement, including its legal limitations in a democratic republic, a survey of the primary duties and responsibilities of the various law enforcement agencies, a delineation of the basic processes of justice, an evaluation of law enforcement's current position, and an orientation relative to law enforcement as a vocation.

COURSE OUTLINE

INTRODUCTION TO LAW ENFORCEMENT

T-PSC 101

OBJECTIVES: (1) To present the history of law enforcement, the status of the law enforcement officer, and the philosophies of law enforcement work.
(2) To provide a basic orientation to police administration and the ethics of the profession.
(3) To create an awareness of the crime problem, its causes, and the methods of prevention and solution.

COURSE HOURS PER WEEK: Class, 5; Laboratory, 0.

QUARTER HOURS CREDIT: 5.

PREREQUISITE: None.

OUTLINE OF INSTRUCTION:

I. Philisophical Background to Law Enforcement

A. Man and state

B. Justice and law

C. Law enforcement and punishment

II. History of Law Enforcement

A. Ancient and feudal backgrounds

B. English precedents

C. The "Peelian Reform"

D. Development in the United States

III. Constitutional Limitations

A. Law enforcement and personal liberties

B. The Bill of Rights and major enforcement problems

C. Constitutional law enforcement

IV. Agencies of Law Enforcement

A. Local agencies

B. State agencies

C. Federal agencies

D. Related agencies

E. Private agencies

V. Processes of Justice

A. Introduction to processes of justice

1. Pre-trial processes

2. Trial and post-trial processes

VI. Evaluating Law Enforcement Today

A. Human relations

B. Efficiency, morality and legality

C. Research areas and current trends

SUGGESTED TEXT:

LAW ENFORCEMENT TRAINING

RADAR SPEED DETECTION

This course outline details the minimum orientation and training requirements necessary to equip an uninformed officer in the use of radar. In general this orientation will be conducted in two parts. The classroom instruction will be conducted in the morning and the on-the-job training in the afternoon.

I. CLASSROOM INSTRUCTION

A. Origin of Radar

B. Description of Instruments
   1. Controls
   2. Radar Beam
      a. Shape of beam
      b. Length of beam and range
      c. Effect of opaque and transparent materials
      d. Tuning fork

C. Explanation of Doppler Principle

D. Angle Error

E. Importance of Antenna Aim

F. Range Setting

G. Comparison of Frequencies and Wavelengths
   1. Standard broadcast station
   2. Mobile transmitter
   3. Radar (10,525 MC)

H. Interpreting Meter Readings
   1. Vehicle size
   2. Distance of vehicle from the antenna
   3. Operating on two and four lane roads
   4. Types of interference

I. License Requirements
   1. Operator - station
   2. Six month instrument check
   3. FCC form 452-C

21558

16. Approximately how many hours of operation did he have with the particular radar in question? On all radars?

17. Did he perform tests for proper equipment function on the date of citation?

18. What did these tests consist of?

19. What is the source of power to the radar instrument?

20. What happens when a moving object enters the radar beam?

21. What happens when a non-moving object is in the radar beam?

22. What was the approximate angle of the radar beam in relation to the automobile travel?

2. Radar Test Information
   a. Calibration Check
   b. Time of Check
   c. Manufacturer of Radar and Serial Number of Instrument
   d. Vehicle Number
3. Enforcement Action Information
   a. Citation Number
   b. Vehicle Registration Number and State
   c. Time
   d. Speed
4. Remarks

P. Meeting Court Requirements
   1. Discussion of Typical Questions, pertaining to Radar activity, that may be asked in court.

II. ON-THE-JOB TRAINING

A. The On-the-job Training will usually be conducted
   1. Removing the Radar Equipment from the case
   2. Mounting the equipment on the vehicle
   3. Selecting site
   4. Positioning the vehicle at the site
   5. Performing necessary instrument checks
   6. Observing and interpreting the meter indication.
   7. Placement of the Radar in the case
   8. Repeating as often as necessary.

Instances will arise when an attorney representing a person cited for speed violation will question the condition of the radar and the manner of its use. It is wise, therefore, for an officer to take certain precautions for meeting these objections.

If the officer has properly prepared and adjusted the radar equipment, no difficulty should be encountered on the witness stand in meeting defense questions. In addition, the officer should keep an activities log and enter necessary information during his tour of duty, not at the end of the day.

Listed below are some typical questions asked in court:

1. What is the name and model number of the radar instrument used at time of citation?

2. What company manufactured the instrument?

3. What time was the radar activity started?

4. Where was the radar instrument located on date of citation?

5. What was the direction of traffic being surveyed?

6. How many lanes in the particular section of highway were under surveillance?

7. What are the names of the component parts of the radar system? Where was each component set up?

8. Where was the patrol car parked in relation to the highway?

9. How many officers were working at the particular radar instrument site? If more than one, where were they located?

10. How did the officer determine, without question, that the radar instrument was recording the speed of the proper automobile?

11. Is radar subject to outside influence other than moving automobiles? How do you detect the difference between a traveling auto and a false return?

12. Was the operator ever trained in the use of radar equipment?

13. What was the duration of the schooling and the number of hours per day spent in training?

14. Did the officer have "on-the-job" training in the use of radar?

15. Did the officer have a training certificate?

J. Consideration in Selecting an Operating Site
   1. Traffic and road characteristics
   2. Instrument placement
   3. Enforcement action
   4. Need

K. Preparation for Use
   1. Mounting and positioning radar components
   2. Connecting instrument components
   3. Meter calibration
   4. Type of adjustments

L. Specific instruction on the type of Radar used by the police department
   1. Instrument check lists, etc.

M. Precautions - Don'ts
   1. Don't connect the power cable before connecting the antenna cable.
   2. Don't calibrate before proper warm up.
   3. Don't strike the tuning fork (when used) on a material that will nick or damage the metal.
   4. Don't disconnect the antenna cable while power is connected.
   5. Don't aim the antenna (with power on) at any opaque object closer than 6 feet.
   6. Don't attempt to re-mount the antenna with the power "on."
   7. Don't switch antenna heads between radar instruments.
   8. Don't drop.

N. Anti-Radar Devices Used by Some Motorists.
   1. Radar detectors
   2. Jamming devices
   3. Other methods.

O. Enforcement Activity Records
   1. Site information
      a. Date
      b. Location of Site
      c. Direction of Vehicle Travel
      d. Type of Road - local, arterial, expressway
      e. Legal Speed Limit - Posted, Unposted.
      f. Type of Area - Residential, Commercial
      g. Weather Conditions

CHAPTER I

Curriculum Development

In this changing world we must find ways of overcoming resistance to new things.

We begin with eight assumptions:

The curriculum is what the school sets out to teach.

Change is a major characteristic of the world today.

As the world changes, so must the curriculum of the schools.

Curriculum change is the responsibility of all the people.

Implementing curriculum change is primarily the teacher's task.

The focus of curriculum study is change in the classroom.

The process of curriculum change should reflect concern for the teacher's readiness.

Curriculum change is possible to some degree in all types of schools.

The general emphasis in this Handbook is upon change in the teaching-learning processes, centering upon the teacher. The intent is to suggest principles and procedures that create a good environment for change--change that comes about because teachers feel it is necessary and desirable, not simply expedient.

ABSTRACT - Developed by the Vocational-Technical Division of the North Carolina State Board of Education, this outline is for instructor use in planning a course on construction methods and equipment. Specific objectives are to: (1) study methods and equipment for various types of excavations, and for highways and pavement construction, (2) study types of piles, and techniques of steel erection, and (3) investigate residential building methods and details. The material is presented in outline form consisting of 17 major topics, and is recommended for use with the text by R.L. Peurifoy entitled "Construction Planning, Equipment, and Methods." A list of suggested references is included. A related document is available as VT 013 318, also in this issue. (GEB)

Course Description

T-CIV 217 CONSTRUCTION METHODS AND EQUIPMENT

Excavating methods and equipment used in building and highway construction; pile driving; construction techniques and equipment used in reinforced concrete buildings, bridges, lift-slabs, thin-shells and folded plates, erection methods and equipment for structural steel buildings and bridges, carpentry in house and heavy timber construction; construction safety. Field inspection trips.

21564

COURSE OUTLINE

T-CIV 217 CONSTRUCTION METHODS AND EQUIPMENT

OBJECTIVES: (1) To study methods and equipment for various types of excavations.
(2) To investigate equipment and methods used in highway and pavement construction.
(3) To study different types of piles, and the methods and equipment used in driving them.
(4) To study techniques, details, and equipment pertaining to steel erection, timber and concrete construction.
(5) Introduction to lift-slab, thin shell and folded plate construction techniques.
(6) To investigate residential building methods and details.

COURSE HOURS PER WEEK: Class, 3; Laboratory, 2.

QUARTER HOURS CREDIT: 4.

PREREQUISITES: T-DFT 102, T-CIV 102.

OUTLINE OF INSTRUCTION:

I. Classification of building construction according to:

A. Size of project

1. Small

2. Medium

3. Large

B. National Board of Fire Underwriters

1. Fireproof construction

2. Semifireproof construction

3. Heavy timber (mill building) construction

4. Ordinary construction

5. Frame construction

C. Usage

1. Public buildings

21565

2. Institutional buildings

3. Residence buildings

4. Business buildings

5. Storage buildings

II. Preparation of job site

A. Clearing and grubbing requirements

B. Equipment used for clearing and grubbing

1. Tractor and dozer

2. Root rakes

3. Winch and cable

4. Dragline

5. Chain saws

C. Stripping

1. Requirements

2. Methods

D. Grading

E. Drainage

III. Excavation

A. Methods of excavating

1. Open excavation with unsupported slopes

2. Sheeting and bracing for shallow excavations

3. Sheeting and bracing for deep excavations

a. Timber sheet piling

b. Steel sheet piling

c. H-piles and lagging

d. Single-wall cofferdams

21566

g. Scraping units

(1) Crawler-tractor-pulled scrapers

(2) Wheel-type tractor-pulled scrapers

h. Bulldozers

2. Factors affecting the selection of equipment to use

a. Available equipment on hand

b. Type of equipment that could do job most economically

D. Dredging and hydraulic excavation

IV. Drilling and blasting rock

A. Equipment used in drilling

B. Drilling methods

C. Blasting processes

V. Drainage and stabilization

A. Ditches and sumps

B. Pumps

C. Wellpoint systems

D. Miscellaneous methods

VI. Highways and pavements

A. Equipment and methods used in earthwork operations

1. Roadway and drainage excavation

2. Drainage structure excavation

3. Embankments

a. Special treatment of foundations

b. Transportation of materials

c. Compaction

f. Soldier course

g. Header course

h. Rowlock course

3. Mortar joints for masonry

a. Flush cut

b. Struck

c. Weathered

d. Concave

e. Convex

f. Raked

4. Types of construction

a. Solid brick walls

b. Hollow brick walls

B. Concrete pavement construction methods and equipment

1. Preparations and preliminary finishing of the subgrade
2. Placing of forms
3. Final subgrade preparation
4. Installation of joints
5. Batching of aggregates and cement
6. Mixing and placing paving concrete
7. Finishing concrete pavements
   a. Hand finishing
   b. Machine finishing
      (1) Mechanical spreader
      (2) Transverse finishing machine
      (3) Longitudinal finisher
8. Curing

C. Asphalt pavement construction methods and equipment

1. Preparation of foundations for asphalt pavements
2. Hauling and spreading asphalt plant mixes
3. Compacting asphalt plant mixes
4. Asphalt mixed-in-place construction
5. Surface treatments and seal coats

VII. Piles

A. Types of piles

1. Wood-sheet piling
2. Steel-sheet piling
3. Timber piles
4. Precast concrete piles

21569

THE AIM OF THIS HANDBOOK

The specific aim of this Handbook is to help schools to make better use of co-operative study-action in improving the curriculum. Special emphasis is placed on the use of outside consultant services, particularly those from colleges and universities, in developing ideas and in putting them to work.

The writers assume that all suggested ways of curriculum improvement will be examined by the local leadership to determine the extent to which they apply to the local situation.

In developing this theme, the writers are conscious of some serious criticisms which will be made:

1. There is evidence that the colleges and universities and their associated study councils in most cases have had relatively little effect in changing elementary and secondary education.

2. There is a reasonable fear on the part of personnel of the elementary and secondary schools, and of state education departments, that colleges and universities will attempt to control the direction of public school curriculum or be unsympathetic to the aim of educating all children and youth.

Let us point out in reply that many study councils limit themselves to exhortation, inspiration, and advice on curriculum problems. The evidence on the few groups which personalize their services and adapt their advice to the local situation may be quite different.

As to the second point, this publication strongly recommends a partnership of colleges and public schools, not domination of one by the other. Each has much to offer to American children and youth.

WHO SHOULD READ IT?

If a school leader is in accord with the aim of this Handbook and its assumptions, he might wish the following groups of people to read it:

Those Who May Be Directly Involved in Curriculum Development

The administrator in charge
The curriculum committee chairman
Each committee member
The consultant

Those Who Must Provide Support for the Program

Building principals
Assistant superintendents
Supervisors
County school leaders
High school department chairmen
School board members
P. T. A. officers
All interested teachers

ABSTRACT - Developed by the Vocational-Technical Division of the North Carolina State Board of Education, this outline is for instructor use in planning a course on construction of roads and pavements. Specific objectives are to: (1) analyze the effects of various types of loads on flexible and rigid pavements, (2) study subgrades, including types, properties, preparation, stabilization, and testing, (3) teach the design of bituminous surfaces and concrete pavements, and (4) study techniques and details pertaining to pavements. The material is designed in outline form with 13 major topics included, and is recommended for use with the text by Laurence Hewes and others entitled "Highway Engineering." Two other suggested references are listed. A related document is available as VT 013 317, also in this issue. (GEB)

Course Description

T-CIV 227 CONSTRUCTION OF ROADS AND PAVEMENTS

Construction practices for various types of road building, including soil properties, grading, subgrading, base courses, drainage, embankments, compaction, and formwork. Design, construction, and testing of rigid portland cement concrete and flexible bituminous pavements. Field inspection trips.

COURSE OUTLINE

T-CIV 227 CONSTRUCTION OF ROADS AND PAVEMENTS

OBJECTIVES: (1) To analyze the effects of various types of loads on flexible and rigid pavements.
(2) To study subgrades, including types, properties, preparation, stabilization, and testing.
(3) To teach the design of bituminous surfaces and concrete pavements.
(4) To study the techniques and details pertaining to the control, construction, and testing of both flexible and rigid pavements, and perform the necessary tests.

COURSE HOURS PER WEEK: Class, 3; Laboratory, 2.

QUARTER HOURS CREDIT: 4.

PREREQUISITES: T-CIV 217, T-CIV 218, T-CIV 202.

OUTLINE OF INSTRUCTION:

I. Pavement types and wheel loads

A. Definition of pavement types

B. Comparison of highway and airport pavements

C. Wheel loads

1. Effective contact areas

2. Distribution of wheel loads to subgrade

a. Elastic soil deformation

b. Consolidation soil deformation

c. Plastic soil deformation

II. Stresses in flexible pavements

III. Stresses in rigid pavements

IV. Pavement behavior under moving loads

V. Rigid-pavement pumping

21580

VI. Subgrades

A. Investigation

B. Classification of soils

1. American Association of State Highway Officials (AASHO) classification

2. Public roads administration classification

C. Important properties of soils in highway construction

1. Density

2. Supporting power

3. Permeability

4. Compressibility

5. Elasticity

6. Capillarity

D. Tests of subgrade soils

1. Direct measurement of supporting power

2. California bearing-ratio method (CBR)

3. Shrinkage

4. Density

a. Relation between moisture content and density

b. Optimum moisture content

E. Effect of subgrade movements on wearing surfaces

1. Elastic rebound after compression

2. Shrinkage and expansion

3. Frost heave

4. Slides in cuts and fills

5. Slips

21581

6. Settlement of fills

7. Lateral flow of soft subsoil

8. Erosion by surface water

F. Preparation and stabilization of subgrades

1. Drainage

a. Side ditches

b. Pipe drains

c. Underdrainage

(1) Blind drains

(2) Tile drains

d. Culverts

2. Removal and replacement of defective soils

3. Mechanical manipulation

4. Use of blanket courses

5. Use of foundation courses

6. Surface treatment

7. Subsurface waterproofing

8. Use of admixtures

9. Consolidation

10. Measures for the prevention and correction of slides and slips

11. Control of erosion

G. Stability of fills and slopes

H. Problems of construction

VII. Granular bases and subbases

A. Typical grading requirements

WHY CURRICULUM DEVELOPMENT?

Why is it important that educators constantly work on the improvement of curriculum? We suggest these reasons:

1. To keep up with our constantly changing world, communities, and schools. Affecting us are the population explosion, urbanization, changing neighborhoods, inter-group problems, and changes in values. There are evident today new technologies, new forms of energy, and the rise of new nations and ideologies.

2. To keep up with the extension of knowledge. We have much more content from which to select, many new and valuable tools of learning to use. To discard those aspects of traditional pedagogy which have become ineffective should be a first order of business. The time lag between the invention of more effective practices and their general usage may be greater in education than in any other profession.

3. To evaluate carefully the many pressures for change. Proposals for revision are being initiated not only from within the profession, but by representatives of academic disciplines, by large foundations, and by proponents of new technologies. Via mass media, pressures for some of these proposals reach our school boards. We must not become merely faddists or opportunists in education.

A Great Task for School People

The task for teachers and administrators is not necessarily to invent new practices and discover new knowledge. Scientists, inventors, psychologists, professors of education, historians, sociologists, and scholars in a host of other fields are doing this. Our main task is to apply these new skills and knowledges to our local situations.

The problem, then, is how to help teachers and administrators become aware of cultural change and new knowledge, recognize their roles in modifying the curriculum, and set up programs of school improvement appropriate to the students they teach.

How do we proceed to work on the problem? The writers believe that the essential labor must be performed at the local level. Only when a school staff becomes personally involved in innovation, experimentation, and research are lasting changes likely to be implemented in the classroom.

On the following page are presented several alternative approaches for working on the local scene. In the chapters which follow, the writers develop suggestions for local leadership in curriculum improvement, with particular reference to the function of the outside consultant.

Factors Which Block or Support Change

Whatever the approach, a realistic assessment of blocking and supporting factors must be made. Then a setting must be created in which teachers can best work with intellectual freedom and responsibility.

This must not be a setting in which the participants are indifferent, confused, or battling, but where they know what they are doing and work together to achieve common goals.

ABSTRACT - This manual represents a modern approach to the teaching of driver and traffic safety education and is designed to encourage the teacher to place emphasis on development of positive student attitudes toward driving. Topics are: (1) Introduction to Driver and Safety Education, (2) Orientation to the Automobile, (3) Operational Skills, (4) The Driver as a Mechanism, (5) Laws, Regulations, Ordinances, and Their Environment, (6) Physical Factors that Control Driving, (7) Perceptual Skills and Traffic Strategy in the Country, (8) Perceptual Skills and Traffic Strategy in the City, (9) Perceptual Skills and Traffic Strategy on Limited-Access Highways, (10) Social Problems and Driving, (11) Consumer Education, (12) Engineering, (13) Laboratory Instruction, and (14) Emergency Driving Procedures. Each unit is divided into an overview of the topic, unit problem, expected outcomes, content, teaching suggestions, and pupil activities. Two optional sections are appended. (GB)

SOME WAYS OF CURRICULUM DEVELOPMENT

Here are five ways of going about the improvement of curriculum and instruction at the local level. Beside each we present some major pros and cons.

THE WAY	THE BEST THAT CAN BE SAID ABOUT IT	THE WORST THAT CAN BE SAID ABOUT IT
1. REWRITE COURSE OUTLINES	This can be helpful for those who do the rewriting and for new teachers.	The outlines often get lost, are ignored, or serve as excuses to avoid trying new things.
2. FIND BETTER TEXTBOOKS AND DEVICES	There are many excellent new texts, varied teaching materials, and helpful devices and machines on the market to supplement any program or course.	Texts and devices do not necessarily motivate people to learn. Also, great reliance on texts or commercially developed programs means that the curriculum is being determined by the financial interest of the publisher, who may turn out to be an inhibitor of change.
3. SEEK FUNDS FROM VARIOUS SOURCES	A great amount of money is available from federal, state, and private foundation sources for varied jobs which need doing.	These agencies can exert a subtle and indirect but real control over the direction of education by choosing where to place or not place their money, and by diverting local matching funds from other worthwhile areas.
4. REORGANIZE FOR BETTER INSTRUCTION	The process of searching for new organization and scheduling forms can help clarify our total needs and goals. It will appeal to the business and lay public for its efficiency.	Reorganization does not necessarily change people. It is possible to reorganize a whole school system without affecting the quality of teaching in a single classroom.
5. ENLIST THE HELP OF COLLEGES	The work of college or university consultants in an active partnership with public school personnel may be a most helpful experience to both. Other proposals on this page may be utilized in this joint effort.	Some colleges and universities may merely wish to publish more research, exhort the public schools to raise their standards, or determine the public school curriculum without examining the total problem.

UNIT TOPIC III - OPERATIONAL SKILLS

OVERVIEW OF THE TOPIC

At this point students must become aware of the fundamental skills such as turning corners, backing, turning around, positioning of car, signaling, speed control, stopping position, lane change, and parking the vehicle.

These operational skills are not necessarily taught at one time but are covered as the students progress (i.e., parallel parking may be taught after student becomes proficient in backing).

The fundamentals of traffic foresight should be developed from the beginning, and the procedure necessary for "reading traffic" should constantly be emphasized so that the student can anticipate traffic hazard potentials.

UNIT PROBLEM

To develop basic operational skills during first driving experiences

To develop the ability to anticipate hazards

To acquire the advanced skills necessary for the safe, efficient operation of the motor vehicle

UNIT TOPIC III - OPERATIONAL SKILLS

EXPECTED OUTCOMES	CONTENT
The student becomes aware of:	Simple tracking and turning paths
Traffic situations and patterns	Changing gears
Back-in-turn with no following traffic	Braking, backing, turning, and back tracking
Pull-in-turn with no approaching traffic	Stopping procedure for intersection control
Traffic problems involved in these maneuvers	. Stop line . Cross walk . Point of conflict
Problems of controlling the car in close maneuvering	Backing in street or driveway on right and pulling in on left
Problems of coordination and perception in controlling the car	Parking procedures
	Identification of problems and hazards of each
	Orientation to on-street parking an reduced-risk traffic situations (li to moderate traffic in residential areas)
	Scanning for the identification of problems and intersection procedures

UNIT TOPIC I - INTRODUCTION TO DRIVER AND SAFETY EDUCATION

UNIT TOPIC II - ORIENTATION TO THE AUTOMOBILE

OVERVIEW OF THE TOPIC

The safe, efficient operation of a motor vehicle requires that each new driver understand the function of the various instruments, controls, and safety features within his reach; be familiar with the positions of all instruments and controls; be able to interpret them with only a swift glance; and manipulate them without taking his eyes off the road.

UNIT PROBLEM

To learn to use a

d ing while rols		Transparencies of gauges and dials.
	Steering technique	Discuss hand-over-hand steering vs. "walking the wheel."
	Use of accelerator	
	Use of brake	Discuss left- vs. right-foot braking.
	Use of clutch	Discuss car ventilation.
	Use of mirrors	Discuss blind spots.
	Use of eyes	PUPIL ACTIVITIES
	Hand and turn signals	Compare school car with family car.
	Changing drivers in traffic	Discuss warning lights vs. gauges.

UNIT TOPIC I - INTRODUCTION TO DRIVER AND SAFETY EDUCATION

OVERVIEW OF THE TOPIC

Each high school driver and traffic safety education pupil should become familiar with the fundamental objectives of the course. The insurance premium savings and full licensing privileges at age 17 are of minor importance compared to the long-range objectives of the program. However, a discussion by the teacher of these immediate pupil objectives may develop a more receptive attitude on the part of the entire class toward the program's long-range goals.

UNIT PROBLEM

To develop kn
are requisite to t
to the people of t

CHAPTER II

What Kind of Leadership

Many a school administrator has said: "I know we need curriculum revision. But I don't have the time to do it. And how do I get teachers interested?"

Many a teacher has said: "I know we need curriculum changes. But if I have to sit through one more meeting where a committee just talks and talks--I'd rather go home and peel the potatoes."

What kind of leadership will surmount these common obstacles to change? We believe it is shared leadership, where the official leader takes into account the ideas of the group. Shared leadership takes many forms and is at least as old as this ancient poem from the Chinese:

A leader is best
When people barely know that he exists,
Not so good when people obey and acclaim him,
Worst when they despise him.
"Fail to honor people
They fail to honor you";
But of a good leader, who talks little,
When his work is done, his aim fulfilled,
They will all say, "We did this ourselves."

DRIVER AND SAFETY EDUCATION

CONTENT	TEACHING SUGGESTIONS
The purposes of the program:	The school medical department should screen students for any physical defects or impairments. Thus, an instructor can suggest compensations or, in doubtful cases, require a student to procure a clearance from the motor vehicle department.
Insurance requirements and licensing privileges	Have students read mimeographed requirements for course completion.
Accident statistics	Arrange for a meeting with parents or send home a letter to parents.
Conduct in the classroom and in the vehicle	Distribute texts.
The values of driver and traffic safety education	Have students keep a notebook of supplementary materials.
How to interpret statistics, charts	
Criteria for evaluation of students (student's progress chart)	

UNIT TOPIC III - OPERATIONAL SKILLS

EXPECTED OUTCOMES	CONTENT
The student becomes aware of:	Simple tracking and turning paths
Traffic situations and patterns	Changing gears
Back-in-turn with no following traffic	Braking, backing, turning, and back tracking
Pull-in-turn with no approaching traffic	Stopping procedure for intersection control
Traffic problems involved in these maneuvers	. Stop line . Cross walk . Point of conflict
Problems of controlling the car in close maneuvering	Backing in street or driveway on right and pulling in on left
Problems of coordination and perception in controlling the car	Parking procedures
	Identification of problems and hazards of each
	Orientation to on-street parking and reduced-risk traffic situations (ligh to moderate traffic in residential areas)
	Scanning for the identification of problems and intersection procedures

Stopping procedure for intersection control

- Stop line
- Cross walk
- Point of conflict

Backing in street or driveway on right and pulling in on left

Parking procedures

Identification of problems and hazards of each

Orientation to on-street parking and reduced-risk traffic situations (light to moderate traffic in residential areas)

Scanning for the identification of problems and intersection procedures

TEACHING SUGGESTIONS

Off-street use of stanchions and cones

- Develop off-street drills

Stress proper body and hand positions.

Encourage proper use of rearview mirror.

Develop on-street routes that facilitate practice.

Begin use of anecdotal records.

PUPIL ACTIVITIES

Study material in N.Y.S. Driver Manual.

Students should diagram and explain the identification of the problems encountered and maneuvers necessary to accomplishing tasks.

UNIT IV - THE DRIVER AS A MECHANISM

OVERVIEW OF THE TOPIC

The driver is the most important single element in traffic safety. It is generally believed that people drive as they live and, therefore, it is important for all drivers to evaluate their total personalities and realize the potential effect of this on their driving. The driver who is able to adjust in a positive way to the many stresses and tensions of living can become a safe and responsible driver.

Many possible distracting factors may affect the driving of youngsters such as socioeconomic background, intelligence, personality, motivation, and age. These factors must be recognized and understood if we are to influence a behavior pattern in the young driver.

Insights and meaningful experiences must be provided so that students may understand behavior and human error as they relate to traffic accidents.

The fact that several states have enacted legislation requiring thorough physical examinations for all drivers over age 65 indicates the importance of the physical condition of the driver in relation to the safe operation of a motor vehicle. If each driver knows and understands his own physical limitations, and learns to compensate for them, his driving can be made safe and enjoyable.

UNIT PROBLEM

The relationship between the human characteristics of drivers and the motor vehicle accident problem

Attitude and behavior as significant factors in traffic safety

Attitudes relating perceptions to performance

Self-preservation as an instinct

Attitudes being subject to change as the acquisition of knowledge and maturity increases

The relationship between good physical condition and driver performance

The adjustment of driving patterns to physical limitations

UNIT V - LAWS, REGULATIONS, ORDINANCES, AND THEIR ENVIRONMENT

OVERVIEW OF THE TOPIC

Many of our existing traffic regulations have been derived from custom, but the Vehicle and Traffic Law was developed to control the increased volume of vehicles.

Voluntary compliance with traffic ordinances will reduce the need for additional enforcement and legislation.

Drivers' licenses are granted by the State Department of Motor Vehicles, and all persons applying for the driving privilege must pass preliminary tests administered by that department.

A student desiring to take a road test before completing a State-approved driver education course must complete a special course of classroom instruction prescribed by the Motor Vehicle Department.

Driver and traffic safety education pupils must understand that they may retain the privilege of driving only so long as they maintain satisfactory driving records. Violations become a permanent part of their records.

Violations become a permanent

UNIT PROBLEM I

To teach the beginning driver the following about vehicle and traffic laws:

Vehicle traffic laws reflect the history of transportation.

There are federal, State, and local laws and regulations for drivers and vehicles.

UNIT PROBLEM II

That the driver understand the following about police traffic supervision:

Enforcement of vehicle and traffic laws is one of the responsibilities of the police.

Police effort and driver cooperation help provide safe and efficient highway transportation.

The value of enforcement is highly dependent upon the proper disposition of charges by the courts.

Selective enforcement should be directed toward the alleviation of violations known to be accident causative.

Traffic law enforcement reflects "community climate."

UNIT IV - THE DRIVER AS A MECHANISM

EXPECTED OUTCOMES	CONTENT
To develop understandings and awareness in beginning drivers of the following:	Mental perspective. . Responsible maturity . Irresponsible immaturity . Environmental influence and behavior
Physical disabilities which affect driving.	
The effect of emotions on safe driving.	Relationship of age to driving patterns.
The behavioral patterns that produce bad risks as drivers.	Effect of physical fitness on body endurance, test performance, and driving ability.
The student is able to:	Disabilities. . Permanent - visual, auditory, muscular . Temporary - fatigue, carbon monoxide, medications and drugs, alcohol, and other depressants.
Drive when physically fit.	
Drive with controlled emotions.	
Compensate for temporary disabilities, i.e., fatigue.	
Evaluate vehicle and environmental limitations.

CONTENT

Mental perspective.

- Responsible maturity
- Irresponsible immaturity
- Environmental influence and behavior

Relationship of age to driving patterns.

Effect of physical fitness on body endurance, test performance, and driving ability.

Disabilities.

- Permanent - visual, auditory, muscular
- Temporary - fatigue, carbon monoxide, medications and drugs, alcohol, and other depressants.

TEACHING SUGGESTIONS

Administer and interpret a psychological test such as Mann's Personal Attitude Survey.

Administer and interpret psychophysical test: reaction time, night vision, depth perception, visual acuity, peripheral vision.

Discuss accident statistics of older drivers and handicapped drivers compared to drivers under 25. Emphasize why the young driver's record is so bad.

Arrange for the school psychologist to talk to the class about the psychological manifestations of good and poor drivers.

Discuss the difference between an accident and a crash.

Show and discuss the film: "Anatomy of an Accident."

PUPIL ACTIVITIES

List medicines found at home that produce drowsiness and discuss their implications.

Identify conflicts leading to tension.

Discuss ways of resolving conflicts.

UNIT V - LAWS, REGULATIONS, ORDINANCES, AND THEIR ENVIRONMENT

EXPECTED OUTCOMES

The student becomes aware and develops an understanding of:

Traffic laws as the responsibility of the State and local municipality

Special conditions for Federal Government intervention (National Highway Safety Bureau)

What constitutes the uniform traffic code

The necessity of laws for regulating traffic

The process involved in making and enforcing laws

The part enforcement plays in reducing accidents

The responsibility and privilege of having a driver's license

How to obtain and keep a license

The function and problems of the Department of Motor Vehicles

CONTENTS

Vehicle and traffic law as o lined in the drivers manual:

- Uniform vehicle code
- State & local ordina
- Interstate travel
- Interstate compacts

The law and its enforcement:

- The role of federal, and local agencies
- Enforcement, selecti nonselective barrier proper enforcement
- Effects of verdicts

The licensing privilege:

- Test requirements
- Permit and license
- Issuance, renewal
- Suspension, revocati and cancelation

DEVELOPING SHARED LEADERSHIP

A leader is someone who causes others to get something done. The leader who tries to involve others in determining what should be done and how to do it--the leader who tries to help each person involved to make such judgments with the greatest concern for others--is called democratic. The preference here is for this democratic leadership, with its tendency to develop leadership in others.

For the purposes of this booklet the terms shared, evolving, emergent, and democratic leadership will generally be used interchangeably, even though each word has its own particular connotation.

Add a Dash of Reality

Every school system has those who have been given official responsibility for the children, staff, curriculum, resources, buildings and grounds, and so on. Such responsibilities require thousands of decisions, big and small. Time and circumstances often affect the extent to which an official--or status leader, as we shall call him--can consult with others.

Status leaders may find it easy to make decisions that have little impact on human behavior. But when people must change, others in the schools may be far more able to promote the change.

The need for change must be felt by teachers. Status leaders should learn how to encourage this without chicanery, cajoling, or other questionable techniques. Attention to the theory of evolving or emergent leadership may help.

Leadership Evolves

This theory says that leadership is a product of the situation, the group, and the person. There cannot be a leader without a group, nor an effective group without a leader. The leader is the one who is most sensitive to the needs of the group and helps to establish its goals and carry them out.

Leadership, therefore, is any contribution which helps the group define and attain its purposes.

Although it is helpful to the leader to possess certain desirable traits--intelligence, the ability to express himself, self-confidence, and others--it should be remembered that these traits are not the special gift or property of any individual. We all possess them in varying degrees, and can make our contributions to leadership accordingly.

According to this theory everyone may be a leader at one time or another. There will usually be an official or status leader in a purposeful group, but this is not incompatible with the idea that the real leader at a given moment may be someone else. This evolving, emergent, or shared leadership is variable and may rotate as the situation changes.

The idea of shared leadership is not new--it has been the basis of ancient republics and modern democracies. It has existed in primitive civilizations. Today it has support from historians, psychologists, and sociologists.

The writers accept the theory that leadership evolves, and have based the remaining chapters of this Handbook on its inherent assumptions.

Some References

The implications of shared leadership are discussed at length by Miel (20). Excellent treatments may also be found in Burnham (13), Douglass (17), Shane (27), Wiles (33), and ASCD 1960 (7).

UNIT TOPIC VI - PHYSICAL FACTORS THAT CONTROL DRIVIN

OVERVIEW OF THE TOPIC

Man has been ingenious in using nature's laws propel himself and his car. These same natural for can injure or destroy him if he fails to consider them in his driving. If he allows a difficult situ tion to go beyond a certain point, the laws of phys take over and the result is out of his hands.

Adverse conditions such as darkness, slippery pavement, fog, sleet, and snow make observance of these natural laws of prime importance.

The automobile industry is attempting to desig the vehicle with built-in safety devices and equipment to compensate for driver indifference to or ignorance of physical laws.

UNIT TOPIC IX - PERCEPTUAL SKILLS AND TRAFFIC STRATEGY ON LIMITED-ACCESS HIGHWAYS

OVERVIEW OF THE TOPIC

On limited-access highways, rear-end crashes and running off the road are the two principal types of accidents caused by higher speeds.

These highways are rapidly increasing in number, and special techniques must be developed to enable the driver to appreciate the safety of the limited-access highway and yet be aware of its hazards.

UNIT PROBLEM

To acquaint the beg
ems of limited-access dr

To enable him to co

UNIT TOPIC VIII - PERCEPTUAL SKILLS AND TRAFFIC STRATEGY IN THE CITY

OVERVIEW OF THE TOPIC

Most crashes in the city occur at intersections generally at moderate speeds. Other major causes of high frequency accidents are left-turn conflicts, improper lane changing, following too close, and failure to yield right-of-way.

In the city traffic there are many more opportunities for vehicle conflict. Therefore, strategy is of utmost importance.

CAN SHARED LEADERSHIP WORK?

It would be surprising if most school staffs were ready for the application of the concept of evolving leadership. Most faculty members have had little experience with this.

Many teachers have heard the democratic theory proclaimed, only to find that the proposal was a gesture, a mere verbalism. They will tend to be especially suspicious the next time they hear the idea mentioned.

What other resistances may be expected when an administrator tries to share his leadership? What could be done about them? The chart below suggests some ways.

Charting a Strategy for Changing Attitudes Toward Democratic Leadership

Staff Perceptions of Attempts at Democracy	What the Leader May Do To Modify the Perceptions
Some teachers will doubt the leader's sincerity--will be afraid of being hoodwinked.	Don't go overboard to prove it. Take time. Carefully delegate responsibility and back up staff decisions even though there may be some doubtful ones. Be sure the scope of authority delegated is clear at the start.
Some simply won't want the responsibility.	Start with those who do. Most teachers want responsibility on some problem. Be sure that the range of problems on which teachers are consulted is wide enough to attract most of them.
Some will see their vested interests jeopardized by open examination.	Try to start with problems that do not seriously divide the staff and badly threaten the balance of power.
Some will be afraid of the new learnings involved in democratic operations.	In the orientation and planning with groups be sure to account for participation roles that involve some very simple, as well as complex abilities.
Some will question whether this kind of decision-making is part of their job.	Be careful to involve staff in problems that are clearly connected with instructional policy and procedure.

Discuss the value of seat belts.

UNIT TOPIC VII - PERCEPTUAL SKILLS AND TRAFFIC STRATEGY IN THE COUNTRY

OVERVIEW OF THE TOPIC

A large percentage of traffic deaths and injuries occur in the countryside due to the higher rate of speed and the driver's inability to cope with the rapidly changing traffic picture.

Some of the hazards that can lead to this accident potential are secondary crossroads, hills, curves, farm equipment, pedestrians, disabled vehicles, and outdated and poorly engineered highways.

Contrary to popular opinion, most serious accidents occur on straight, dry, country roads in clear weather.

TANDARDS-1963-A

UNIT TOPIC X - SOCIAL PROBLEMS AND DRIVING

OVERVIEW OF THE TOPIC

Motor vehicles have given the American people a great freedom, but this freedom is being abused. The traffic toll for a holiday weekend is often described as "a national disaster." But even this fails to arouse people to demand a solution.

Many Americans will either ignore or reject research statistics about the relationship of alcohol and traffic accidents.

National Safety Council figures, based on accident reports, indicate that nearly one out of every two fatal motor vehicle accidents involved a drinking driver, and that one out of every four adult pedestrians killed in motor vehicle accidents had been drinking. Drivers who had been imbibing caused over half of the Christmas-New Year's fatal accidents.

It is interesting to note that none of the studies indicated "drunken driving." The term "had been drinking" characterizes the driver who staggers to his car and then weaves recklessly in and out of traffic. But as dangerous as this individual is in traffic, it is the so-called "social drinker," the person who believes that one or two drinks do not affect his behavior, who is the real problem. Scientists who study the nervous system have found that the first few drinks often have a very serious effect on behavior.

The driver education teacher's role includes teaching pupils how important this problem is to our society.

UNIT PROBLEM

The beginning driver unders
about the effects of alcohol an
driving:

That use of alcohol and drugs d
driving efficiency

That alcohol may act as a depre
as a stimulant

That use of alcohol and drugs m

UNIT PROBLEM

The beginning driver understanding the following about the effects of alcohol and drugs upon safe driving:

That use of alcohol and drugs definitely decreases driving efficiency

That alcohol may act as a depressant rather than as a stimulant

That use of alcohol and drugs may be manifestations of existing emotional maladjustments

That custom and lack of understanding by the public sometimes encourage social drinking before driving

That alcohol may not outwardly affect the skills of the driver, but it makes the driver unfit to drive

21636

UNIT TOPIC IX - PERCEPTUAL SKILLS AND TRAFFIC STRATEGY ON LIMITED-ACCESS HIGHWAYS

EXPECTED OUTCOMES	CONTENT	TEA
The student becomes aware and develops an understanding of: The importance of preparing the car and driver for travel Entering, traveling on, and leaving limited-access highway Traveling to the next exit if one overshoots the exit desired The importance of a good space cushion	Present concepts of perceptual skills of limited-access highways: . Aim high . Get big picture . Keep one's eyes moving . Make oneself known . Leave oneself an out Present skills for traffic strategy: . Types of interchanges . Trip planning and knowing the exit . Use of rumble strip . Purpose of center mall . Proper use of acceleration lanes . Lanes of travel . Passing maneuvers . Speed control with traffic flow . Avoid bunching . Emergency procedures . Highway hypnosis . Use of deceleration lanes . Problem of being velocitized	Visual Ai . Por Spa . Per on Pamphlets manufactu Use of ma projector Motor Veh Live" pro Explain l access hi Resource PUP News clip Trip plan Have stu breakdown Have stu distance Have stu periodic

a good

CONTENT

Present concepts of perceptual skills of limited-access highways:

- Aim high
- Get big picture
- Keep one's eyes moving
- Make oneself known
- Leave oneself an out

Present skills for traffic strategy:

- Types of interchanges
- Trip planning and knowing the exit
- Use of rumble strip
- Purpose of center mall
- Proper use of acceleration lanes
- Lanes of travel
- Passing maneuvers
- Speed control with traffic flow
- Avoid bunching
- Emergency procedures
- Highway hypnosis
- Use of deceleration lanes
- Problem of being velocitized

TEACHING SUGGESTIONS

Visual Aids

- Portions of the Smith System of Space-Cushion Driving
- Perception of Hazards #2 film on limited-access driving

Pamphlets and brochures from auto manufacturers.

Use of magnetic board and overhead projector.

Motor Vehilce Department "Learn and Live" program.

Explain local variations on limited-access highways.

Resource person in traffic safety.

PUPIL ACTIVITIES

News clipping, charts, and posters.

Trip planning.

Have students identify some common breakdown problems.

Have students discuss why following distance is so important.

Have students discuss the value of periodic rest.

21634

SAFEGUARDS FOR THE LEADER

If a status leader starts out to develop and share leadership, he is bound to be tested. Teachers who do not understand the many pressures on administrators will hope for too much. The doubters and skeptics will have to be shown.

The point is that the leader must not promise more than he can deliver. And knowing what one can deliver takes honest self-study. Here are some questions to help the leader check himself before he embarks on a democratic venture with his faculty.

A Leader's Checklist for Self-Evaluation

The leader should attempt to analyze himself with questions such as these:

In what situations am I likely to be most anxious or fearful?

What things tend to annoy or anger me most?

How badly do I need the center stage in school affairs?

How do I take criticism and in what areas can I take it most and least?

In what affairs must I have the veto power?

How interested am I in helping the staff to take responsibility--or is this simply a gimmick to let people think they have authority?

What proportion of my leadership time is usually devoted to each of the following: (a) telling the group what to do, (b) promoting my ideas or manipulating the group, (c) listening to the group's ideas, (d) joining the group as a member in arriving at a common decision?

Such questions, answered as honestly as we know how, may tend to limit the scope of initial ventures in sharing leadership. But better to start modestly and succeed than to over-commit and fail.

Questions on Delegating Responsibility

Fuzzy delegation of responsibility accounts for many disappointments and conflicts in efforts to share leadership. Here are some guidelines:

Be sure that other status leaders understand what is being delegated, especially if it might interfere with their authority as they see it.

In describing what is being delegated, give specific illustrations of what is and is not within the scope of authority of the person to whom it is delegated.

Develop standards or criteria for group recommendations. These should be based upon:

Examination of all the facts available locally

Expert opinion

Research

Be sure that delegating responsibility does not merely mean "passing the buck."

Setting Personal Standards

Buffeted as the leader is likely to be, it might help him to use a leadership inventory of some kind. The checklist that follows might serve this purpose.

UNIT TOPIC XI - CONSUMER EDUCATION

OVERVIEW OF THE TOPIC

Purchasing, insuring, and maintaining automobiles will be a major financial decision to be faced by most of the class members.

The students should consider these factors when purchasing a car: amount of money available, uses for the car, whether the car is new or used, the past history of the particular car, economy of operation, future trade-in value, insurance, and operating costs.

Special emphasis should be given to methods of financing the purchase and proper insurance coverage.

UNIT PROBLEM

That drivers and vehi

be given to methods of
roper insurance coverage.

UNIT PROBLEM

That drivers and vehicle owners understand the following about automotive products and services available to them;

The percentage of an individual's income that is allocated to the purchase and maintenance of a motor vehicle

Selecting new and used vehicles that are safe and efficient to operate and maintaining them in good operating condition

Purchasing insurance

Follow manufacturer's recommendations for preventive maintenance

Exploring various available sources of financing before signing an installment loan agreement

Reading contract carefully and making sure all blank spaces are filled in before signing

Lowest purchase price or cheapest maintenance may not always be the best value

UNIT TOPIC X - SOCIAL PROBLEMS AND DRIVING

EXPECTED OUTCOMES	CONTENT
The student becomes aware of: The effect alcohol has on an individual The laws relating to drinking and driving The detrimental effect of alcohol consumption upon safe driving	Alcohol consumption is a major cause of automobile accidents and fatalities. . Removes sound judgments . Removes inhibitions . Slows reaction time . Affects muscular coordination . Blurs vision Effects of barbiturates Effects of "pep pills" Effects of narcotics

be developed to enable
e safety of the limited-
aware of its hazards.

UNIT PROBLEM

To acquaint the beginning driver with the problems of limited-access driving

To enable him to cope with these problems

UNIT TOPIC XI - CONSUMER EDUCATION

EXPECTED OUTCOMES

The student becomes aware of:

The danger of making financial commitments which he cannot possibly meet

The reduction in operating costs attributable to proper maintenance and safe, skillful driving

The advantages of comparison shopping

The benefits of paying cash

Variance in credit costs

The relationship between safe driving and reduced insurance premiums

The student is able to:

Select a car to fit his needs and pocketbook

CONTENT

TEACHING SUGGESTIONS

Compare the advertised price with dealer's "Blue Book."

Assign readings from text and Driver's Manual.

Invite an insurance representative and/or auto mechanic to talk to the class.

Discuss Vehicle and Traffic Law, Sections 250 and 345 - Insurance.

Exhibit and discuss sample insurance policies.

PUPIL ACTIVITIES

Develop a checklist to help determine the type of car students need and can afford

Role playing - dealer and buyer

Evaluate a typical guarantee

Discuss magazines such as Consumer Reports

UNIT TOPIC XII - ENGINEERING

OVERVIEW OF THE TOPIC

Entire cities are being built or redesigned to accommodate to the anticipated increase in numbers of automobiles. Engineers no longer are concerned with simply providing new homes, stores, or office buildings. New highways and parking facilities must be built to accommodate the motoring public. Cars and highways of the future must be safe and efficient. By 1975 anticipated vehicle registration will surpass 111 million.

Automobile manufacturers are directing their engineers to produce safer cars. Safety is becoming a major selling point.

It has been predicted that highway and traffic engineering will prevent highway collisions in the future. Anticipated speeds in excess of 100 miles per hour on the highways of tomorrow are expected to be safer than 40 miles per hour on today's roads.

Many states and localities have not as yet accepted the *Manual on Uniform Traffic Control Devices*.

The Federal Government's interest in automobile safety will cause safer cars to be manufactured and will improve the State traffic safety program.

The engineering approach is a three-phase program essential to any long-range traffic safety plan.

Slides . Film strip . Magnetic board . Charts Assign students supplementary information to reinforce textbook materials. Teacher demonstration of desired maneuvers in the vehicle followed by student participation and evaluation. Each lesson should be introduced with specific driving objectives. Instructor demonstrations should portray examples of expected student performance. Laboratory instruction should be an integral part of classroom instruction to reinforce student learning experiences. PUPIL ACTIVITIES Encourage home practice to reinforce teacher-demonstrated procedures.

21650

UNIT TOPIC XIV - EMERGENCY DRIVING PROCEDURES

OVERVIEW OF THE TOPIC

After a student has mastered basic driving techniques and procedures, he should be exposed to the common emergency driving techniques he may encounter. The teaching at this point should be directed toward a familiarization of potential emergencies and their possible solutions. At no time should the teacher expose students to a situation unless they are in complete control. The safety of the student means more than the completion of the problem.

UNIT PROBLEM

To acquaint the beg
emergencies and prepare
sions to prevent potenti

21651

A LEADERSHIP INVENTORY

This is a self-evaluation checklist for the leader. He should give himself a rating ranging from 0 (low) to 5 (high) on the extent to which each item is true.

Recognizing Limitations and Capabilities

_____He realizes the limits of his own authority and responsibility.

_____He understands the real power structure in his school system.

_____He recognizes his personal limitations. He realizes that he doesn't know everything.

_____He is willing to acknowledge when he has been mistaken or when he has had a change of viewpoint.

_____He knows what his strengths are. He sees new vistas and doesn't lose sight of them, even if the going gets difficult.

Knowing the Group

_____He helps his group to know one another better.

_____He acquaints himself with the strengths and weaknesses of the individuals in the group, and is sensitive to their needs.

Functioning as a Member of the Group

_____He helps the group see the overall picture of what might be done.

_____He informs the group of the limits of his own and the group's authority.

_____He helps create a feeling of need to do the job, whether he or the others previously saw the need or not. He helps the group determine that the job is possible.

_____He helps the group set reasonable, definite and solvable goals.

_____He involves the group in work assignments based on each individual's needs, drives and abilities.

_____He does not rely on exhorting, but works along with the group and sets a good example.

_____He gives the group praise, recognition, and high acceptance.

Securing Results

_____He gets something done without doing it all himself.

_____He tests his results by looking at how the people of his group are affected, and whether he has developed leadership within the group.

_____He achieves reasonable goals. He accepts gradual achievement when he can see that a more rapid pace would not bring lasting results.

Implementation of seat belts, laminated glass, safety locks

Research in highway construction

Definition of engineering

Role of the State Traffic Commission

Reading and interpreting road maps

Figuring the percentage of tax dollars apportioned to highways

Differences between planned and unplanned cities

TEACHING SUGGESTIONS

Show and discuss films: "Survival Car I and II".

Discuss specifications for Federal vehicles.

Invite a local traffic engineer to talk to the class.

Display cross sections of different types of roads (concrete - blacktop).

PUPIL ACTIVITIES

Discuss and utilize a spot map.

Observe local traffic flow for good and poor examples of highway engineering.

Analyze causes of traffic delays and have various groups offer suggestions for eliminating these delays.

Have a discussion on suggestions for future improvements in automobile safety design and equipment.

Study local traffic regulations and determine their causes and effectiveness.

Plan a trip across the country using the Interstate Highway System.

21646

UNIT TOPIC XIII - LABORATORY INSTRUCTION

OVERVIEW OF THE TOPIC

It is imperative that before the student performs a maneuver he is able to identify the elements of safe-driving performances which are most crucial to the safe completion of that driving maneuver.

The classroom should be utilized to identify and emphasize driving procedures and techniques that eliminate conflicts with moving traffic.

Loss of valuable laboratory-in-car-instruction time would be avoided if the student knows the maneuver he is to perform and the hazards he is likely to encounter.

UNIT PROBLEM

ABSTRACT - Intended to supplement classroom instruction rather than serve as a complete text, this publication has been prepared as a basic training manual in the field of accident investigation for cadets at the California Highway Patrol Academy. Topics are (1) Vehicle Crashes--The Problem: The Solution, (2) Accident Investigation--A Professional Challenge, (3) Accident Investigation Procedure, and (4) Determination of Speed from Skidmarks. The document is also designed to serve as a ready reference for investigators in the field. (GB)

APPENDIX I - THE MULTIPLE CAR METHOD OF TEACHING DRIVER EDUCATION (OPTIONAL)*

OVERVIEW OF THE TOPIC

The goal of driver educators is to reach all students eligible for instruction in the secondary school. School administrators are constantly concerned with per-pupil cost and frequently give this reason for not expanding the program during the regular school day.

Some solution of this problem may be realized by using the Multiple Car Method** or "Range Program" as it is commonly called. Experience has shown that the quality of the program remains high, more students are taught, and per-pupil cost drastically reduced.

Essentially the Multiple Car Method involves teaching by utilizing an off-street area on which a number of vehicles are used simultaneously to provide laboratory instruction under the supervision of one or more teachers.

A school employing two teachers and needing a third teacher would be well advised to investigate the advantages offered by the Multiple Car Method in teaching driver education.

---

*In all instances, when planning and/or organizing an optional driver education method, reference should be made to State Education Department Policies.

**Section V, paragraph 5.1, Multiple Car Facility states, "Special approval from the State Education Department is required by schools for multiple car driving range programs before such instruction can be given. All enrolled pupils must receive a minimum of 18 periods (1 per week) of range instruction, two pupils per vehicle; and a minimum of 18 periods (1 per week) of actual practice on public streets and highways, using four pupils per vehicle."

UNIT PROBLEM

To assist the be
operational skills

To increase teac
or more

To increase pupi
to 100 percent

To provide a sa
student may efficien
with special concent

FINDING AND DEVELOPING NEW LEADERS

The obligation of leaders to generate more leadership is brought out by Miel (20). Here are some brief suggestions for developing new leaders. For an extended treatment see ASCD 1960 (7).

On-the-job experience. In every school and within every committee, there are temporary or sub-leadership jobs to be done. Use these opportunities to try out and train potential leaders. Coach these people and be generous with praise when the job is done well.

Local leadership meetings. Call leaders, sub-leaders, and potential leaders of a particular curricular project together for planning. Use part of the time for informal, friendly evaluations of the type of leadership being offered.

Laboratory sessions. A number of universities conduct extended laboratory or workshop sessions where leaders and potential leaders live and work together, often for two-week periods during the summer. Emphasis may be placed on self-involvement, role-playing, interaction analysis, group dynamics or other aspects of leadership.

RECOMMENDED FOR PURCHASE

This list might form a priority for purchase for a school's professional library on leadership in curriculum development. The complete bibliographical listing is found in the list of reference sources in the back of this booklet.

ASCD 1960 Yearbook. Leadership in Improving Instruction.

ASCD 1960 Yearbook. Role of Supervisor and Curriculum Director in a Climate of Change.

Snow-day activities

TEACHING SUGGESTIONS

Teacher must have additional college course or suitable inservice training.

During first few lessons, emphasis is on group instruction. In later lessons this will change to a combination of group and individual instruction.

After the first lesson, introduce at least one new maneuver each period.

Use simple, direct commands.

Avoid double meaning terminology.

Preface commands with "all cars" or car number.

Limit directions to essentials.

Know and watch the trouble spots.

Alert students to potential dangers.

Develop a sound emergency plan to use if need arises.

PUPIL ACTIVITIES

An alert, advanced pupil may be assigned to a car with a slow learner to act as a teacher's assistant, giving individual instruction to the slower pupil. This plan has merit.

APPENDIX 2 - THE SIMULATOR METHOD OF TEACHING DRIVER EDUCATION (OPTIONAL)

OVERVIEW OF THE TOPIC

The use of simulation to supplement the laboratory phase of Driver and Traffic Safety Education was adapted from the process of training airplane pilots on the Link Trainer during World War II.

Driving simulators use electro-mechanical devices designed to represent the driver's compartment in an automobile. The student operates the unit just as he would a real vehicle on the highway. His reactions to driving conditions, which are projected on a wide screen in full-color motion pictures, are monitored and evaluated by a recording device.

The simulator provides numerous opportunities for varied driving experiences which the student might never encounter in the dual-control program. Control of traffic conditions, through the use of film, simplifies learning experiences by allowing the student to focus his attention on the development of fundamental skills without distraction.

Simulation does have some limitations such as the lack of movement, the restricted field of vision on the screen, the false security of not being in "live" traffic, and the difference in the feel of the operating devices.

Nevertheless, simulators are helping to meet the quality-quantity-cost challenge facing driver education and should be investigated closely by schools with sufficient enrollment.

UNIT PROBLEM

R METHOD OF TEACHING DRIVER EDUCATION (OPTIONAL)

	CONTENT	TEACHING SUGGESTIONS
of	Orientation to simulators	Use a simulator as a supplemental tool to achieve course objectives.
lls	Steering skills	Devise a system for handling ignition keys.
	A drive in the automatic transmission vehicle	Prepare students for the film and interject relevant comments during the film showing.
ing	Shifting skills	Follow film with discussion of key situations.
nses	A drive in the manual shift vehicle	Use instructional aids such as traffic board blackboard, film strips, and slides to accomplish objectives
ocedures	Highway driving	Use the simulators in manual and automatic. This allows the teacher to move about, when they are on automatic, to aid students.
ving	Traffic driving	Teacher should use:
	Defensive driving	. Light pointer to key situations . Blindfold techniques for checking procedures such as starting vehicle and locating controls . Projector on silent position to give students a realistic situation
	Special driving techniques	
	Expressway driving	
	Angle parking and turning maneuvers	
	Parallel parking	
	Adverse weather driving	
	Driving emergencies	
	Test films	

PUPIL ACTIVITIES

Implement silent film with narration

21666

Students in simulators react to real situations projected on a wide screen.

CHAPTER III

Getting Started

The spark that sets off curriculum change may come from administrators, teachers, or anyone.

Who decides to do something about curriculum development? The question is not whether curricular decisions must be made, but rather who should make them and how. The decision may result directly from administrative leadership or from questions raised by classroom teachers who face the task of finding the best and most effective ways of working with students. This daily challenge gives rise to many questions that can only be resolved by curriculum study.

It is recognized that there is no one way of creating concern for the curriculum. Much is dependent upon the philosophy of a particular school, the relationships which exist between the administration and staff, and the nature of the community and its demands. However, without the impetus of inspired administrative leadership little will take place in curriculum development.

Recognizing, therefore, the key role of the administrator, let us examine the process by which a program of curricular study might be effectively undertaken with the full support of the administration.

Important references for this chapter are Douglass (17), Pratt (25), and Shane (27).

CHAPTER 1

VEHICLE CRASHES - THE PROBLEM; THE SOLUTIONS

In our modern industrial society motor vehicles are an economic necessity. Without them our economy would collapse because neither people nor materials would be capable of movement sufficient to sustain it.

When there is movement of physical objects there is conflict between them. The degree of conflict depends upon the space available for movement and the number and size of the objects in motion. While chemists can effect compounds of materials which combine without occupying additional space, drivers of motor vehicles cannot so blend their conveyances without causing damage, injury, or death. Efforts to enlarge the space available to motor vehicle traffic continue as streets are widened and more freeways are constructed. Yet, every citizen knows that the number and size of motor vehicles increase apace. Thus, conflict is inevitable. Traffic crashes continue to cause damage and injury so extensive that all citizens are affected either directly or indirectly.

Traffic collisions cannot be eliminated, but they can be reduced to an acceptable minimum. The problem is attacked by utilizing the techniques of EDUCATION, ENGINEERING, and ENFORCEMENT. Through education public interest is stimulated in order that all persons not only understand the extent of the problem, but they also become aware of the skills and attitudes necessary to reduce collisions. Properly engineered highways and vehicles reduce both the causes and effects of traffic crashes. The enforcement of governmental regulations, aimed toward the reduction of traffic conflict, accidents, and their resulting damage and injury, both guide and direct highway users in order to solve our society's problem. Forceful implementation of each tine of the three-pronged attack against the traffic problem of our society is essential in every community of our country.

Information essential for effective planning of the "Three E's" is obtained mainly through accident investigation. Reports of accident investigations provide one of the few sources of unbiased information available. These investigation reports perform a great public service. Accident investigation is the cornerstone of the foundation of any program of traffic supervision. Without accurate information upon which to base plans, this function cannot be progressive or accurate.

If planning to prevent accidents is to be valid and productive, it must be based upon consideration of accident causes. To achieve this there must be careful investigation, together with complete and accurate reporting, to determine cause.

The question then arises, which accidents should be investigated and reported? Fatal accidents alone, fatal and injury only, or to develop the complete picture should all collisions be investigated?

The number of damage or injury accidents which occur for each fatality is unknown. Their incidence in cities, with slower speeds, is greater in proportion to fatal accidents than in rural areas where higher speeds are attained. In California during a sample year, accidents were reported in the ratio of 1 fatal to 28.6 injury to 42.0 damage accidents. This was a statewide total based upon 3,041 fatal collisions. All crashes were not reflected because many damage and some injury accidents were not investigated or reported.

If planning were based on fatal accidents alone, only 3,041 of the total 218,255 accidents would be considered. This is but a small percentage of the total. If planning is expanded to include injury accidents, the base is expanded to 90,306 collisions. However, 127,949 (59%) of known crashes would still not be considered; thus, planning would still be based on only 41% of the total.

The investigation and reporting of all known accidents is suggested for two reasons--adequate planning and good public relations. No matter how minor an accident may appear to one not directly affected, it is an important matter to those people actually involved. They look to the police for help. Although police are primarily concerned with the criminal aspects of the investigation, parties concerned expect (and are entitled to) an impartial evaluation of the circumstances in order that the rights of all may be protected. The investigator should not attempt to establish civil liability or fix the blame, but he should impartially record the facts so that in any future civil action an unbiased, intelligent, and complete factual record will be available.

However, the time necessarily consumed by investigation of all accidents known to a department may not be available. There is validity in the argument that prosecution of the violator who has caused an accident is too late. It is proper to consider that the officer's presence on visible patrol, which deters other potential accident causing violators, is time better spent than in the investigation

of minor property damage collisions--especially those in which no violation is immediately discernible. Today, many of the larger departments find it necessary to curtail their investigations of such minor accidents because their available manpower is insufficient.

Instead of basing investigations upon the severity of accidents the professional approach would appear to be consideration of the incidents in terms of possible violations--an enforcement viewpoint. Thus, a one-car fatality in which the victim was alone in his car might take a minimum of investigation (in spite of its grave consequences), as contrasted to a property damage accident involving violations by both drivers. As an enforcement officer, the investigator must not lose sight of his objective. Obviously, the same amount of time cannot be devoted to all minor accidents because there are too many of them. Evaluation of the occurrence in terms of possible violation appears to be a firm basis to use as a guide to investigative effort.

Prosecution after accident is the most equitable type of enforcement. Much time is spent in apprehending and citing drivers whose violations might cause an accident. If these drivers are prosecuted, it follows that in all fairness prosecution should be instituted against those whose violations have caused accidents. By pointing out the relationship between collisions and violations, the public may be brought to realize the need for strict enforcement of all traffic laws as a preventive measure. The entire enforcement program will be bolstered by public support as the realization grows that if traffic violations were not combatted by enforcement, a terrific increase in highway casualties would surely result. The philosphy of "haven't they suffered enough already?" is no valid reason for failing to prosecute. The fleeing felon who is seriously wounded during an escape attempt undoubtedly suffers from his wound. Society, however, spares no effort to keep him alive in order that he may stand trial for his offense. Why should personal suffering, no matter how great, limit prosecution of the traffic violator?

This type of prosecution is readily understood by the general public. People who witness, or are involved in an accident where there is a violation, expect the police to do something about it. They are perplexed if nothing is done. Prosecution of violators is an objective lesson to the general public, acts as a strong deterrent, and lessens opportunities for further deaths, injuries, and economic losses. It presents the officer to the public as someone who is doing something tangible for them. It engenders a feeling of protection which, in turn, creates a desirable

relationship. To the violator it points out that all traffic laws must be obeyed.

In contrast to the crime rates, which steadily increase, the accident rate not only can be but has been lowered. In the face of increased travel, California's mileage death rate (deaths per 100 million miles traveled) has dropped. In 1949 the rate was 7.7, in 1959 was 5.3, and in 1969 was down to 4.5. The population death rate (deaths per 100,000 population) has also been reduced. In 1949 it was 29.1, but by 1968 it had been lowered to 24.5. While it is true that the number of fatalities attributed to motor vehicle collisions has risen, it can be seen that the attack against the problem has been successful. The statistics prove that the chance of a California citizen being killed in an accident has been significantly reduced.

21675

CHAPTER 2

ACCIDENT INVESTIGATION - A PROFESSIONAL CHALLENGE

Accident investigation is not only important, it is interesting. The investigator deals with human problems, frailties, and suffering. In turn, he renders a service to humanity. His immediate action may directly save one life and indirectly many lives. Each investigation presents a new challenge, calling for the utmost in skill, knowledge, and ability.

Because of lack of motive, accident investigation is different from other types of police investigations. If the occurrence were planned, it would no longer be an accident. Accidents happen unexpectedly, without design, or by chance. The element of surprise is a part of any traffic accident.

During recent years, scientists have turned to the word "crash" in preference to the term "accident" in reference to traffic collisions. Their belief is that traffic collisions are CAUSED OCCURRENCES rather than incidents involving chance alone. In almost every traffic crash there has been human failure--someone has made a mistake by neglecting to obey the dictates of either traffic laws or defensive driving. For police investigative purposes, however, both terms may be used interchangeably since the officer's objective is to determine collision cause. Accident investigation offers a challenge to the investigator and gives him an unlimited opportunity to use his initiative, skill, and experience to uncover the factors which caused the crash.

Accident investigators are given the opportunity to perform a public service. Not only are the results of investigations utilized in research, but officers render immediate assistance to those involved in the collision. They become the protectors of the suffering. The public views with favor actions to expedite traffic and assist victims of accidents. Such positive actions are necessary in order to elicit public support of enforcement organizations.

Many major arrests will follow accident investigation. These include arrests for misdemeanor and felony drunk driving, manslaughter, hit and run, reckless driving, auto theft, and other crimes. Obviously, a great amount of care must be used in case preparation. Essential evidence must be recognized, identified, and properly preserved. The investigator must be careful to make a thorough

21676

investigation, prepare his case meticulously, and present his case well in court. The officer whose work is inadequate will fall short of accomplishing his duty to the people whose rights he is sworn to defend, protect, and uphold.

In civil cases, too, courts have come to rely upon the investigating officer for unbiased and informed testimony. The California Highway Patrol has acquired an enviable reputation in this connection, and judges and attorneys have come to give great weight to the officers' testimony. The investigator should always be conscious of this, and he must realize that a poor investigation or presentation of evidence will destroy that which has taken years to build.

In view of the importance of accident investigation, it becomes apparent that the successful accident investigator must possess certain qualities and abilities. This will assure that the task is accomplished satisfactorily from the standpoint of the individual, the public, and the department which the investigator represents.

The first of these is ENTHUSIASM. The individual must be interested in his work, zealous, and anxious to do the best possible job. Each new investigation must be accepted as a challenge. Lacking enthusiasm, the operation becomes routine, something to be accomplished with a minimum of time and effort. The completed investigation will fall short of the quality which is necessary. It will be a recording, not an investigation.

DETERMINATION is another essential for the successful investigator. He must possess tenacity of purpose to do a competent job, get the job done and done well, or the investigation will lack that completeness which marks the good report.

The investigator must possess SINCERITY. He must truly believe in his work and its importance as a public service. His feelings must direct his actions toward a definite goal. Believing fully that what he is doing is worth doing well, he will be content with nothing less than sincere effort to achieve the best in each investigation.

A sense of RESPONSIBILITY is important--a desire to be an asset to the organization he represents. He must recognize the need to make a thorough investigation, do a proper job of enforcement, write a complete and concise report, and represent the department well at the accident scene. He should realize that investigation goes far beyond mere

21677

recording of readily available information on an official form.

The ABILITY TO COMMUNICATE is essential. As an investigator, he will be expected to know more about the accident than a layman. This information must be so written that any reader will have as much knowledge of the circumstances as the investigator. The investigator's report must contain all his knowledge of the incident. IF, AFTER READING THE REPORT, THE READER CAN ASK A RELEVENT QUESTION REGARDING THE ACCIDENT, THE INVESTIGATOR HAS IN SOME MEASURE FAILED. Either the investigation or the report has been in some way inadequate.

Proper representation of the department at the scene entails the ability to REPRESENT AUTHORITY without a display of excessive command. The officer need not remind people who he is--they recognize him the moment they see his uniform. The investigator is being observed all the time. Some welcome him, some believe in him, but others would like to criticize him. The actions of the officer reflect not only upon himself, but upon his department and the whole police profession.

The investigator must possess INVESTIGATIVE ABILITY. He must be able to interview, observe efficiently and completely, reach sound conclusions, and make his investigation meaningful and valuable. Some fatal accident investigations may be very difficult, as in those cases without survivors. With no witnesses, the accident must be reconstructed from physical evidence alone. There have been attempts to make it appear that victims of murder met death as the result of a traffic crash. Casual examination of the scene would have led to a false conclusion, allowing the perpetrator to escape. In many cases, however, proper application of investigative techniques have uncovered evidence that the incidents were not what they appeared to be, and the responsible parties have been brought to justice. The ability to analyze situations--measure statements against physical evidence and probability--in order that his opinions will approach reality is essential for the investigator.

Dealing as he does with people who are not in a normal situation, the investigator must possess the qualities of LEADERSHIP. It is necessary that he quickly bring order to the chaos existing at accident scenes. He must have the ability to control emotionally and physically upset people. He must use skill and tact in answering or asking questions. An attitude of disinterest or levity is out of place at the scene of any accident. No matter how commonplace or routine the particular incident may appear to the

SELECTING A PROBLEM FOR STUDY

While the administrator is vital in the decision to do curriculum improvement work, he must look to the staff for ideas, reactions and proposals. Unless the final choice of the study topic is based upon the real and felt needs of the classroom teacher, there will not be much self-motivation on the part of the participating teachers. If it is accepted that meaningful curriculum change must include change in teacher behavior, there should be a sincere desire on the part of teachers involved to want to change their methods and habits for the better.

But will teachers feel the need to change? Will such feelings throw too much emphasis on some areas of the curriculum to the neglect of others? The answers seem to be that teachers do feel many needs to change, but the administrator must make sure that gradually their sensitivity to balance in the curriculum is broadened.

Several methods may be used to select a problem. The final choice should hold the interest and support of both administration and staff. Here are some possible approaches:

Build or expand upon an existing program.

Develop a local problem which has been partially defined. Everyday complaints of teachers and parents (e.g., "Why can't they read this material?") might become the basis of a thorough study.

Hold a brain-storming session with the entire faculty or a group of representative members. Compile the ideas and recommendations, and study the most common problems.

Defining and Limiting Tasks

After potential problem areas are explored, the group should settle down to specify the problems on which it will concentrate. Probably there should be two concerns at this time:

What common goals will we have as a group?

What individual or sub-group goals will be set?

This process of goal-setting should not be hurried. Nothing could be more important.

Set goals in behavioral terms, as much as possible. That is, try to indicate how differently things would be done if the goals were being achieved. This helps all concerned really to understand what they are beginning to agree upon.

Reasonable Expectations

Unrealistic goals or expectations, on the part of either administrators or teachers, result in disillusionment.

Administrators, at times, attempt to revise the entire curricula from K-12 or even K-8 as a single year's project when even small divisions of such a continuum represent more than one year's study.

The classroom teacher who has already completed a full day's teaching load cannot be expected to contribute on a daily basis to a curricular study committee's work. But a teacher may rightfully be expected to devote a reasonable amount of time to the never-ending task of curriculum development.

FOREWORD

This publication has been prepared as a basic training manual in the field of accident investigation for cadets at the California Highway Patrol Academy. It is intended to supplement classroom instruction rather than serve as a complete text in itself. In addition, it is designed to serve as a ready reference for investigators in the field.

Success in the field of accident investigation requires continued study and research to keep abreast of new techniques and to refresh the memory of the investigator. It is hoped that use of this publication will awaken the desire for further study.

OFFICE OF THE TRAINING DIVISION

DISTRIBUTION: B

investigator, he must always bear in mind that to the participants there is nothing routine about it. To them it is an unusual, frightening, and sorrowful experience. The investigator must approach his task with empathy. As a further instance of leadership, the investigator must be able to recognize how much authority he can delegate to volunteers, as well as properly evaluate their actions to determine if they will actually assist, rather than hinder him in his investigation.

INITIATIVE is essential. Many times he will not have a supervisor to direct him, so he must be able to work on his own. He must be able to think logically and clearly under conditions of duress and pressure. He must persevere in his endeavor to conduct a thorough and complete investigation with a minimum of guidance and direction.

A basic knowledge of PHOTOGRAPHY will be of value. The investigator must plan his picture for its evidential rather than its news value. He should know where a photograph will help in his investigation and where one will not.

A SENSE OF DUTY to protect the rights of the participants is essential to the investigator. He must strive to get the facts. He must realize the need for conducting an impartial investigation without preconceived opinions to color or slant his investigation to either side. It will help if he considers participants as things, materials, and formulas, rather than people. He should approach the investigation in terms of what each vehicle did in relation to other physical conditions. With this viewpoint, he is less apt to be swayed by prejudices as to age, sex, race, color, occupation, or personality. Any of these may subconsciously affect the unbiased consideration of all the elements which he must collect and evaluate. His report of the investigation must reflect the true accident picture.

Knowledge of these, as well as other police techniques and qualities will help. The successful investigator will always be alert for new knowledge, ideas, and techniques. When he uncovers a new way of doing things, he will pass the information on. Progress in any field is a group effort, built upon the contributions of many individuals. The accident investigator today profits from the experience of past investigators, and he in turn can contribute by making available to others the results of his experience and knowledge.

truck ten feet above the highway has a far different field of view than the driver of a low-slung sports car. Skid marks, gouge marks, tire marks and vehicle position should all be checked and the information recorded in notes at the scene, for both the accident report and possible use when testifying.

In addition to notes, the investigator should make a sketch to aid investigation and preserve information. This sketch should be drawn with north at the top and all wording oriented to this direction. The scale should be large enough to make it clear, yet small enough to show the whole area. Everything that might have a bearing on the accident should be included: length and position of skids; distance traveled after collision; width of streets, shoulder and roadways; distance and height of view obstructions; location of traffic control devices; distance from the pavement to any fixed object which was struck; victims or parts of vehicles; and debris. Distances should be measured, rather than estimated or stepped off.

The investigator should not neglect to locate and record the evidence that may be hidden beneath the vehicles. When making the sketch, vehicles should be treated as transparent, viewed from the top, and evidence should be recorded in its proper location.

Necessary photographs should be taken. They may be a great aid to the prosecution as they present physical circumstances of a case in a manner that is easily understood. Most people are visual minded. A photograph of large or perishable evidence is accepted in place of the original. Include such items as skid marks, footprints, or a body to show the location and type of injury. But before the shutter is snapped, the investigator should ask himself, "What will this tend to prove?" If the answer is "nothing", the photo should not be taken.

The photographer must be qualified. He must know what he is doing and why, for the more important the picture the stronger will be the attempt to discredit or disprove it. A commercial photographer is usually not satisfactory for several reasons. In addition to being expensive, he may not know what is required; he is often reluctant to appear in court; and he may not keep proper data to insure that the photograph will be admitted as evidence. If a commercial photographer is used, the officer should direct the photographer to take the type of picture the officer needs and record exposure and other related data. It should be remembered that these photographs are not for publicity but are evidence, as is the sketch of the scene. Valuable as

they may be, the investigator should not depend on photographs only. They may be an important part of the case, but photographs alone do not constitute a complete investigation.

Pictures of many of the following subjects are often needed as evidence or to complete the records of a case: general scene from driver's viewpoint; point of impact; traffic control devices; skid marks showing length and direction; nature of roadway at location, showing defects; position of cars, victims, and parts of vehicles after impact, showing distances from point of collision; view obstructions or the lack of them; blood, flesh, hair, fabrics, scrape marks, etc., frequently useful in hit and run cases; tire prints; footprints; defects in vehicles involved, such as missing headlight, stickers obscuring driver's vision, trucks lacking turn indicators, etc.; the roadside, to show kind of district; sagging springs of overloaded vehicle; license number of vehicle for identification.

The investigator should also make a sketch. Photographs do not show measurements or dimensions. The photo may be incorrectly exposed, blurred, or otherwise worthless. The accident sketch is the record of the investigator's intricate, personal examination of the scene.

With the information gathered, the investigator should now determine the cause or causes of the accident. He should be very careful in this, as it is one of the most important parts of the investigation. It should be approached in terms of the violation and facts should be gathered to prove the essential elements of the action. It is quite possible that there may be one or more violations on the part of each driver.

What the investigator faces upon his arrival at the scene is the result of a combination of circumstances. He must start from this result and work backwards as his investigation progresses, until at its conclusion he knows the cause or causes of the accident.

CAUSES - RESULTS

Broadly speaking, accidents may be classified as either one of two types, collision or non-collision. The collision may be with another vehicle, train, bicycle, fixed object, pedestrian, street car, animal drawn vehicle, animal, or other type of object. Non-collision may be running off the roadway, overturning in the roadway, or other non-collision, such as fire, falling from a vehicle, or injury

their undirected efforts may hamper rather than help the investigation. Attempts should be made to keep onlookers in a safe location. This at times poses an extremely difficult problem to the investigator.

Where gasoline or oil is spilled on the highway, it may be necessary to request fire equipment to wash it from the pavement, or highway crews may be needed to sand the area to eliminate the hazard. Where fire hazard exists, as from gasoline, liquid petroleum gas, or similar fluids, care should be used in placing flares, onlookers should be warned of the danger of smoking, and if necessary the crowd should be cleared from the area.

Where there is injury, first aid will be necessary. In certain instances this may be the most important thing for the moment and should be given without delay. Where injury is minor, protection of the scene may warrant top priority. Placing flares and directing traffic while a person bleeds to death would undoubtedly be the wrong order of operations, as would bandaging slight injuries before protecting the scene when a high speed road was blocked in an area of low visibility. The investigator must consider each situation on its own merits. First things should come first, regardless of their position on his check list of procedures. An ambulance should be ordered, if required. This is one of the first considerations when there is serious injury. Where there is absolutely a fatality, the coroner must be notified. Any question of doubt as to whether the victim is dead or alive should be resolved in his favor. He should be treated as alive unless, by the very nature of his injuries, there can be no doubt that he is dead.

The investigator must care for the property of those injured. A tow car may be needed, and it should be ordered as soon as it can be conveniently done. If possible, the driver's preference as to towing service should be ascertained, and the tow car of his choice ordered. When the driver is unable to care for his own vehicle, and the investigator orders it stored for safe keeping, a report of stored vehicle must be filled out, and the contents of the car listed and inventoried, securing the signature of the tow truck driver on the inventory form as a receipt for the vehicle and its contents.

GATHERING EVIDENCE - DETERMINATION OF CAUSE

The remaining steps of the investigation come under the headings of gathering evidence for prosecution and determining the cause of the accident. These two objectives are

common to accident investigations and cannot be separated. They go hand in hand. Evidence as to the cause will lead to the violation involved; evidence of the violation will lead to the cause. From evidence and statements of witnesses and participants the investigator must determine the cause of the accident. He must bear in mind that there probably will be more than one cause in any but the most simple type of accident; and where more than one vehicle is involved, there may be one or more violations on the part of each driver.

There are three factors in any accident - the HIGHWAY, the VEHICLE or vehicles, and the PEOPLE involved. All three should be checked for evidence. Whereas it is impossible to get all the facts about everything, the investigator should strive to get all the pertinent facts. If a violation is indicated, an effort should be made to secure sufficient evidence to prove the elements of that violation.

Usually the officer will begin to form an opinion of what happened early in the investigation and will look for evidence to confirm it. At this point care must be taken not to overlook evidence which does not agree with the investigator's theory. Evidence which tends to disprove his first impression may be very important. Things are not always what they seem. The officer must never attempt to distort facts to fit his theory; the opinion must be adjusted to fit the facts. He must never be reluctant to accept negative or conflicting evidence, no matter how convinced he is that the accident happened in a different way. That would be like saying, "Don't confuse me with the facts; my mind is made up."

Every fact, each statement, and every shred of evidence must be analyzed and evaluated in order to get a true picture of what happened. To start with, the investigator is faced with a result. Step by step he must work backwards from that result to find the causes. He must proceed from the "what" of a situation in order to determine, insofar as possible, the "how" and the "why".

A logical first step is to locate and question the drivers and witnesses. This is done by making a quick preliminary check to see that all drivers are present, then attempting to locate witnesses. The investigator should get the operator's license of each driver, determine which vehicle each was driving, then look for persons who might have seen the accident. Many persons may remain at the accident scene until the police arrive then leave before the officer has had an opportunity to question them. An early search for these people may provide the investigator with information which he would not otherwise obtain.

Early in the investigation, it should be determined if it is a hit and run, for the procedures in this type of investigation are different from normal accident investigation. Time is of the essence, and the sooner the hit and run procedures can be put into effect the more likely will be the chance of apprehension.

The second factor to be considered is the vehicle. Much evidence may be developed by thoroughly examining and testing the vehicles involved. It should be determined if all the visible damage was the result of the current accident. The exact location and extent of damage should be noted. Evidence of crumpled fenders and broken glass which does not tie in may be the result of a previous incident. Fresh damage, not connected, may lead to solution of an earlier hit and run. Perhaps the driver's statement is not correct, and damage which it does not explain may lead to the true account of the accident. A check of the mechanical devices, brakes, lights, windshield wipers, turn indicators and mirrors should be made to see if they are adequate. In some cases, operator's licenses are restricted to the operation of vehicles equipped with certain safety devices. The officer should check to determine if safety devices are employed if required. The condition of each tire on the vehicle should be noted and a check made of the front end, providing the damage is not such as to make the test impossible. The driver's statement may give the investigator a clue as to what to look for. Brakes may fail or be faulty or inadequate. Loss of control may suggest a worn steering assembly. A fresh break in the steering mechanism will probably be a result of the accident rather than a cause. Other points to check are lack of safety devices on commercial vehicles, inadequate lighting equipment, defective windshield and vision obscurements. Tire failure is often claimed as the cause of an accident, but many times it is a result rather than the cause. The investigator should know whether or not vehicle failure contributed. In the event of prosecution, the driver may claim vehicle failure as a defense. If the investigator has not checked he will be unable to refute this type of argument. However, if he has made a thorough check, he will have the answers to any possible questions which may arise.

The third factor is the surrounding physical conditions. Any which might have contributed to the accident should be carefully observed by the officer: holes in the roadway surface; loose material on the pavement; the weather; visibility from the driver's path of view, including obstructions to vision such as hedges, trees, poles, signboards; traffic control devices; and warning signs. All observations should be made from the driver's line of sight. The operator of a

Like any other endeavor, accident investigation has its pitfalls:

1. Do not discuss the accident with anyone outside of the department or outside the line of duty.

2. Do not take sides. The investigator is an impartial fact finder.

3. Do not tell any participant he is either blameless or at fault. These are matters for an adversary proceeding.

4. Do not tell anyone you will be a witness for or against him. You will be a witness for no individual. Testimony must be honest and impartial.

5. Do not mention garage charges, repair bills, or civil liability, as these are not part of the investigation.

6. Do not enter into any discussion of a probable or possible fine. This is a court function.

7. Do not be hasty in making decisions as to cause. Consider every possible cause, gather all the evidence, then analyze to exclude factors not involved.

CHAPTER 3

ACCIDENT INVESTIGATION PROCEDURE

Of direct concern to the officer are three equally important reasons for accident investigation. First is the basic police function of PROTECTION OF LIFE AND PROPERTY. This includes the civil aspects of accident investigation. A second reason is to DETERMINE THE CAUSE OF THE ACCIDENT. This is necessary to gather the information required for the department to perform the mandatory functions set forth in the Vehicle Code. The third reason is to GATHER EVIDENCE FOR the PROSECUTION of persons guilty of any violation of the law contributing to the accident. This power is given by Vehicle Code Statute concerning fatal and personal injury accidents, and is extended to property damage accidents (Attorney General's Opinion No. 45-337).

Since the success of any accident prevention program hinges on thorough investigation and complete reporting, it becomes necessary to distinguish between ATTENDING an accident and INVESTIGATING one. It is a comparatively simple matter to go to an accident scene and determine where and when it happened, what happened, who was involved, and record this information on a printed form. This, however, is not accident investigation. It more closely approaches newspaper reporting. The investigator must have this information, but the critical part of his task is to determine HOW and WHY the accident happened. It is in these two areas that the success or failure of the investigator will appear.

Every action of the investigator, from the original accident call to the completion of the report, falls within one of the three reasons for investigating accidents. Steps in normal accident investigation will be grouped under these three broad headings in the order in which they most logically fall.

In order to assure uniformity of understanding, it becomes necessary that certain terms must be narrowly defined. The following basic definitions are in common use in the accident investigation field. These are the meanings used throughout this discussion.

1. ACCIDENT: An undesirable or unfortunate happening; casualty; mishap; anything that happens unexpectedly without design, or by chance.

2. MOTOR VEHICLE ACCIDENT: Any accident involving a motor vehicle in motion that results in death, injury, or property damage.

3. MOTOR VEHICLE TRAFFIC ACCIDENT: Any motor vehicle accident occurring on a highway.

4. POLICE TRAFFIC ACCIDENT INVESTIGATION: Determining what happened, and who and what was involved in a motor vehicle traffic accident, usually at the scene.

5. MOTOR VEHICLE: Any mechanically or electrically powered device (except one moved by human power), not operated on rails, upon which or by which any person or property may be transported or drawn upon a land highway. The load on a motor vehicle is considered a part of the vehicle.

6. STREET OR HIGHWAY: A way or place, of whatever nature, publicly maintained and open to the use of the public for purposes of vehicular travel.

7. TRAFFIC: The term "traffic" shall include pedestrians, ridden animals, vehicles, street cars, and other conveyances, either singly or together, while using any highway for purposes of travel.

There are three types of accident investigations:

1. NORMAL accident investigation will include investigation of those accidents where the principals are present, vehicles approximately as they came to rest, physical evidence unaltered, and with witnesses possibly present.

2. LATE REPORTED, or late investigated, accidents are those in which knowledge of the accident is gained, and investigation, if any, is made after some lapse of time.

3. HIT AND RUN accidents are those in which the operator knowingly causes damage or injury and leaves the scene without identifying himself.

VALUE OF A FIXED PROCEDURE

Some type of fixed procedure is extremely valuable in accident investigation. It is not intended that this should serve as a limitation of the investigator's actions. It should be flexible. Steps should be taken as conditions warrant, rather than by rote. By realizing the need for a fixed procedure, the investigator will use it as a sort of

INVOLVING THE FACULTY

As many of the staff as possible should be involved in curriculum development. The degree of involvement will, of course, change with the readiness, interest, and prior commitments of the staff members.

Committee work is but one way of changing the curriculum. Sometimes change comes faster through work with individual department chairmen, teachers, or intermediate supervisors. These approaches may complement each other.

When a study will affect all of the staff they should be informed and consulted, even if their involvement level remains low. Honest consultation sets the stage for better acceptance of findings or recommendations later.

At what point should the total faculty be involved in a program? The answer is--from the beginning. They must know what is going on. A plan for orientation is suggested in the next chapter.

One caution! Don't let faculty seriously engaged in other studies feel that they are being neglected in favor of the latest fad. This is one of the most common mistakes in introducing new ventures.

WHO ELSE MAY BE INVOLVED?

Many schools will wish to move carefully in the involvement of non-staff members in curriculum building. Such participation, however, holds much promise for the reasons indicated below:

Students

They are the recipients; their needs, as they see them, are important starting points.

Most teachers really care about students; often teachers are more ready to listen to student suggestions than to those of other teachers.

Students tend to say things that the power structure of the school prevents teachers from saying.

Board Members

They are the people who can give strong support to a good curriculum.

They need to know what is going on so they can interpret it to the taxpayers.

They are policy-makers and have a right to know how the policies for which they are legally responsible are being executed.

Parents

Their cooperation and understanding are vital in the long run.

They can help interpret to other parents.

They can reflect needs from a very different slant.

They can help support released time for curriculum study.

Other Citizens

They often become the best resource people the school could get.

They can raise questions that "gentlemen's agreements" among faculty would otherwise block.

They can help to secure resources that might not be available otherwise.

Their understanding is essential to taxpayer support of revisions and new programs.

2142

mental check list. It will make the task easier for the officer, assist in determining the cause and gathering data, tend to make sure that nothing is overlooked in the investigation, give a definite starting point, and help to prevent duplication of effort. A planned procedure impresses the public with the efficiency of the investigator's department and builds favorable public opinion. Officers will find that accident investigation will consume a great part of their time. The better they know the correct procedure, the more reliable their reports will be, and the more pleasant their job will be. When one is familiar with a task it is easier to perform.

PROTECTION OF LIFE AND PROPERTY

In a normal accident investigation there are various steps which may be conveniently grouped under the broad heading of protection of life and property. Not all of these steps will be required in all accident investigations, nor will they always be done in any particular order. The important thing for the investigator to remember is that each investigation should be evaluated in the light of each of these steps, assigning top priority to that which in each instance is most important. The best procedure is a planned procedure which can be adapted to each event.

Before any investigation can commence, the investigator must be at the scene. Therefore, his safe arrival is essential. There are many reasons why the investigation should be made as soon as possible after the occurrence of the accident. It follows, then, that prompt arrival at the scene is also important. The first thing the investigator has to do is get to the scene safely, yet quickly.

Since the accident has already occurred, the investigator can do nothing to prevent it; he should take this fact into consideration and protect his life and others' by driving at a safe speed. Taking unnecessary chances may lead to the investigator being involved in an accident himself. This not only slows down the investigation of the accident he was assigned to cover, but also provides an additional accident which must be investigated. Bad public relations can be caused by the officer becoming involved in an accident while enroute to the original accident scene.

The arrival of the investigator is necessary to protect the scene and other traffic, preserve evidence which might be lost, and in some cases to save life by applying first aid. Another accident may occur because the highway is obstructed. Traffic congestion is usually present, and the investigator must attempt to restore normal vehicular movements. By

prompt arrival he will prevent driver irritation and poor public relations. To those involved in an accident time is fleeting. Each minute they wait seems much longer than it really is. They wonder, and sometimes audibly express their thoughts as to what is keeping the officer. Also important is the fact that witnesses, who might be of great value, often become impatient and leave the scene once their curiosity is satisfied, and the investigator will not derive the benefit of information which he might otherwise receive.

A safe but quick arrival is a challenge to the investigator. One way is to plan the approach over the quickest route (not necessarily the shortest). The investigator must know his area - the short cuts, detours, construction zones and areas of congestion. A few seconds spent thinking out the best route may save minutes of hazardous high speed driving. The officer should start at once upon receipt of the call. A short delay in getting started will have to be made up on the road, and a long delay means that time is lost which can never be regained.

Upon arrival at the scene, the investigator should park safely and conveniently. Consideration should be given to the safety of the officer, the patrol car, and other traffic. Rather than park opposite the accident, where the traffic stream will have to be crossed each time it becomes necessary to return to the patrol vehicle, parking on the same side of the highway will be safer and more convenient. By proper parking, the warning lights on the patrol car may be used to help protect the scene. Safety and availability of the equipment in the vehicle should be considered, as use will be made of the radio, flares, first aid equipment, and the like. Also, unguarded equipment may offer an incentive to potential looters. By safe parking the investigator will help to establish a safe parking and passing pattern, and his task will be much easier if he has the various items he needs close at hand and where they can be kept under observation.

It will be necessary to protect the accident scene to prevent the occurrence of further accidents and to preserve the evidence which the investigator will need. This may require placing flares at night or under conditions of poor visibility. Thought should be given to the proper location of flares to give approaching drivers a chance to slow down before running into the obstruction and to channel traffic into a safe path around the accident. It may be necessary to direct traffic around the scene. In many cases bystanders will volunteer to assist. If their aid is enlisted they should be told what to do; otherwise,

21684

The person who begins his search with a query, "Were there any witnesses to this accident?" will probably not be very successful in finding any. The word "witness" has an unpleasant connotation in the minds of many people. They have been conditioned by motion pictures and other types of entertainment to visualize a witness in court being badgered by the opposing attorneys to the point of acute discomfort, and they want no part of it. The indirect approach is inherently much more productive. The officer should find out from the drivers, if possible, who was the first one they saw or talked to after the accident, then approach these persons and ask them what they saw. They might say that the accident had already happened when they stopped, but they may be able to furnish information as to who was there when they arrived. Thus, by indirection, a witness may be discovered. Many times, while giving first aid or performing some of the other duties incidental to the investigation, the officer may overhear someone telling how the accident occurred. This person may or may not be a witness. He may have talked to someone who did see it, and in this way, too, a witness may be located. A check and recording of the license numbers of the vehicles parked closest to the scene may be valuable. Drivers of these vehicles are most apt to be the first arrivals. Even if witnesses cannot be found at the scene, contacting these drivers at a later date may develop the fact that one or more of them may have witnessed the accident. However, witnesses should be located as soon as possible. Not only are they prone to leave when the excitement is over, but their statements may be valuable in offering leads to develop during the actual interrogation of the drivers. They may also suggest what physical evidence the investigator should look for.

In all contacts with witnesses or potential witnesses, the investigator must act with tact, diplomacy and understanding. It must be remembered that he is asking for something, and that these people have no obligation to tell him anything. Their assistance may be very valuable, if freely given, but if coerced or bulldozed into making a statement, their feeling of resentment toward the interrogator will probably destroy the value of any statement he may extract.

Drivers must be thoroughly checked as to their physical condition. Intoxication is a state which often changes rapidly. Tests for intoxication should be conducted without unnecessary delay. The condition of the driver at the time of the accident is important, not the condition an hour or two after the accident occurred.

within a vehicle. These are not causes of accidents, but the results of unexpected or unconventional behavior of one or more of the elements of the traffic at that particular time. The result may be called the key event, which is the most significant event that happens to each traffic unit involved; for example, collision with another motor vehicle, or running off the roadway.

The direct cause of the accident is the unconventional behavior of a traffic unit which leads directly to the key event. An example of this would be a vehicle that had skidded on a curve. Mediate causes are connected with the accident not directly, but through the direct cause. There may be more than one mediate cause. It is in the area of mediate causes that accident prevention can be effected; the part each factor in the accident plays in its occurrence, that is, the contribution of the vehicle, the driver or pedestrian, and the highway.

Just as the key event is the result of the direct cause, and the direct cause is itself a result of mediate causes, so are mediate causes the result of earlier and more remote causes. There may be many of these, and they may be very remote indeed, such as the habits and attitudes of the persons involved.

For example, in an uncomplicated accident a vehicle runs off the road and overturns, injuring the driver. In this case, the result is an injury accident. The key event would be running off the roadway. The direct cause could be skidding on a curve, which might have resulted from a combination of mediate causes, including a slippery highway surface, excessive speed, smooth tires, improper brake application, and an inadequate signing of the hazard. These in turn may have many early causes; rain, poor driver attitude, insufficient funds for adequate highway signing, construction and policing, lack of education of the driver as to proper care of equipment, and many more acts, neglects or conditions which lead up to mediate causes. The area of improvement in all three phases of traffic supervision fall within the area of mediate causes.

Many of the early causes also offer a field where improvement may be effected, but others are so remote as to be of little immediate concern to the investigator, although they may play a part in the total picture of traffic supervision.

21691

After apprehension is made, it is vitally important that the broadcast be cancelled and all alerted establishments notified. A word of thanks for their cooperation would not be amiss. They might prove useful in a later case.

Good hit and run investigation and reporting is merely digging a little deeper to obtain more facts. It is the small detail which might be easily overlooked which, if found and checked, would start the chain of events leading to apprehending the violator. Success in this field is a group effort, calling for much cooperation with other agencies as well as within the department. Cases are solved by common sense, hard work, and a small amount of technical knowledge.

WITNESS AND DRIVER STATEMENTS

Taking statements from drivers and witnesses is an important part of many investigations. These may simply consist of asking what happened and recording it in the investigator's own words or an informal written statement signed by a witness. In serious cases it may be a formally recorded statement taken by the prosecutor and a stenographer. Statements written and signed by drivers in required reports are confidential; therefore, drivers' statements should not be written or signed by them.

Statements are of value for several reasons. They give the investigator a clue as to what happened and in which direction he should start his investigation; they tend to dissuade a person from changing his story at a later date and may, in some cases, be used to impeach a witness. Even if the person has not signed the statement, the fact that he has given it to the officer may keep him from changing his story. The statement may also be used to refresh the memory of a witness.

The investigator will take statements to assist him in determining facts. By statements, he may place the driver behind the wheel, determine probable point of impact if there were no skid marks, or tie skid marks to a particular vehicle, and establish other circumstances of the accident.

One of the first considerations in taking statements is to talk to the person in private. Many people are reluctant to talk if others are listening. They may be afraid of what the driver or his friends might do if the statement is unfavorable. Spectators may interrupt by interjecting their own ideas, and arguments may start as the result of disagreements between participants.

If possible, the investigator should have the witness or driver tell the story from his general location at the time of the accident. This will serve as a check on his reliability and establish whether or not he could see what he claims. He should be allowed to tell his story without interruption, except as necessary to keep him from rambling too far from the subject. The investigator must be sure he understands what the person means. For example, "I was passing several cars," could indicate the speaker was either meeting or overtaking other vehicles. Words do not always mean the same thing to speaker and listener.

Questions should be objective, positive, specific; not "Where do you live?" but "What is your address, please?" This will tend to save time and make statements concise and pertinent. Statements should be verified with facts and discrepancies pointed out. No attempt should be made to "coach" the witness, but by indicating points of disagreement the person may adjust his recollections.

After the person has finished his statement, if there are any points he has not covered, specific questions should be asked. When the investigator is sure the statement will be complete, he should write it out and have the witness sign it. In some cases it may be appropriate to have a witness write his own statement to keep him occupied and from discussing the event with others. Generally, however, it is better for the investigator to write the statement and have the subject sign. Some people have difficulty putting their thoughts on paper, and their statements will be inadequate. By writing the statement himself, the investigator can be certain it is complete.

When writing the statement as the subject tells it, the investigator may consider deliberately including a few errors in minor details. The subject should correct these when he reads the statement and initial the correction. If he fails to notice the errors, they should be called to his attention. He should then correct and initial them. This precludes the chance of the subject saying he did not read the statement, and by having the pencil in his hand and becoming used to it he is conditioned toward signing the statement when requested.

If the witness refuses to sign, the officer must not insist upon a signature. He should use the positive approach in attempting to get the signature, and if this fails drop the matter. The signature in itself is not essential. Having given the statement to an officer, the subject will be less likely to change his story if he knows it has been recorded.

While listening to a witness' statement the investigator should not be in a hurry to start writing. Some people are reluctant to talk if they know the conversation is being recorded and will not give a statement. Also, the first time they make it the statement may not be adequate and will have to be rewritten, which is time-consuming.

Ordinarily, by the time the investigator is ready to take the statement he will have a good idea as to cause and violation. He should be sure the statement covers all the necessary elements. Care should be taken to cover who was driving, direction of travel, approximate speed, condition of pavement and weather, and to tie in the skid marks, if any, with the appropriate vehicle.

A statement which does not add to the investigator's knowledge of the accident is wasted time, whereas a properly taken statement may prove of great value. However, even if the statement adds nothing to the case it should be preserved. Witnesses have been known to change their stories. If a person who has given a statement in which he declares he knew nothing about the accident should turn up as a witness, the statement taken by the officer would do much to discredit the later testimony.

ENFORCEMENT ACTION

Having gathered the evidence which will support a prosecution, appropriate enforcement action is the next step. In most traffic accident investigations, the offense involved will be an infraction in which case the officer will be precluded from taking enforcement action at the scene due to the legal restraints imposed upon him. In cases where the evidence is clear cut and apparently sufficient to support a charge, the investigator should inform the violator of his intention to file a complaint. In cases where the prosecutor desires the opportunity to review the evidence before he will issue a complaint, the officer should take a positive stand. If he believes there is sufficient evidence, he should tell the violator that it is his intention to ask for a complaint. This paves the way for a psychological acceptance on the part of the violator of subsequent notice that a charge has been filed. If the officer attempts to evade taking a stand by advising the driver that he will make further investigation, confer with his superiors, etc., and a complaint may be filed, the door is opened in the violator's mind for a not guilty plea. He may feel that the officer is not certain in his conclusions, and may be reluctant to accept his guilt to the extent he would if the officer took a positive stand. This points up the fact that an investigation must be complete, thorough, and conclusive.

Should the prosecutor wish to review the evidence before approving a complaint, the violator should be notified as soon as the complaint is filed. If the service of a warrant is his first notice of the court action good public relations suffer. When the officer is empowered by law to take enforcement action at the scene an arrest is in order.

It is good practice for the investigator to review the entire investigation just before he leaves the scene. This serves two purposes. It gives him a double check to assure that all points have been covered and that he has gathered all of the necessary information. A physical recheck may disclose a piece of overlooked evidence, and property of the participants may be found which might otherwise be lost. If two officers are conducting the investigation, they should compare notes to be sure that each has all the necessary information. It takes little time but may be very productive in terms of results obtained.

In some instances, when an investigation is made by one officer alone, it may be advisable to solicit the opinions of other investigators in order to bring the investigation to a well-balanced conclusion.

21692

One possibility the investigator should not overlook is that of the "staged" accident designed to defraud insurance companies by means of non-existent injuries supposedly sustained in a carefully engineered "traffic accident". Some individuals, including attorneys, doctors, and garage proprietors, have conspired to collect damages for fictitious injuries by carefully staging traffic collisions. This type of fraud is difficult to detect.

Officers should carefully observe the demeanor of persons involved, developing good factual detail and watching for inconsistencies or fabrications. If fraud is suspected, careful questioning should be carried on to determine its motive. It may vary from the desire for easy money to outright murder.

Some of the circumstances which might suggest possibility of fraud are lack of witnesses, no plausible reason for the accident, one person freely admitting liability while the other seems to be feigning injury. "Victims" may prefer to seek their own medical care in preference to usual facilities. While these are not conclusive evidence of fraudulent attempts, officers should not close their eyes to the possibility that such a conspiracy might exist.

Before leaving the accident scene, the investigator must be sure that it is in safe condition: vehicles and debris must be cleared from the highway, spilled oil sanded or covered with dirt, flares extinguished and as much evidence of the accident as possible removed. Otherwise, traffic may become involved in additional accidents due to sudden slowing or stopping as drivers observe signs of an accident.

Often it will be impossible to complete the investigation at the scene. It may be necessary to contact additional witnesses to determine the true causes. Drivers or other persons may have been injured and taken to hospitals or their homes after treatment. Sometimes the officer will do this himself, and in other cases this further investigation will be done by officers assigned to accident follow-up. Should it become necessary to interview injured persons, the officer should check with the doctor in attendance before attempting to talk to these people. In some cases their condition will be such that it will not be advisable to interview them. In other cases, they may have been given sedatives or other treatment so that their statements will not be reliable. Each instance will have to be treated on its merits by the investigator. Just as no two accidents will be alike, so no two investigations will be alike. The planned procedure must be flexible, and steps taken in the order called for by each set of circumstances encountered.

The final step of the investigation will be that of making out the accident report on a standard form. In filling out the report, the investigator will be guided by departmental policy, bearing in mind that to be a good report, it should leave unanswered no logical question which might be asked by any of the several agencies which will use it as a source of information. A good investigation will lose much of its value if the information is not transmitted by means of a thorough, accurate, complete report, including in total the Who, What, When, Where, Why, and How of the accident. Similarly, without a thorough, accurate and complete investigation there can be no good report.

In addition to normal accident investigations, two other types will be encountered--late reported accidents and those involving hit and run violations.

Late reported accidents are those which come to the attention of the investigator after some lapse of time. Usually the vehicles involved are no longer at the scene, and much of the evidence will probably have been altered or destroyed. The degree of follow-up of these accidents will usually depend upon the severity. Fatalitites will require a complete investigation. A considerable amount of investigation may be done where serious injury is involved, whereas minor property damage accidents may only be recorded on the official form as simply a driver's report.

HIT AND RUN INVESTIGATION

With the hit and run accident, the officer is faced by a situation wherein he is really conducting two investigations. There is the investigation to determine the cause of the accident, and that to determine the identity of the driver who has left the scene. It is one type of accident where it is readily apparent that a violation has already occurred, that of evasion of responsibility. The officer, however, must not lose sight of the fact that leaving the scene is not a cause of the accident. The investigation, insofar as determining cause, must be complete, thorough and in addition to locating the missing driver.

Hit and run may be a felony, as in cases resulting in injury or death, or may be a misdemeanor, wherein only property damage is involved. In either case, the accident should be investigated just as any other accident, except that the hit and run procedure should be followed.

21694

The elements of felony hit and run, as established by the Vehicle Code, are as follows: A driven vehicle involved in an accident resulting in injury or death; failure to stop immediately (not instantly) at the scene and furnish identification by giving name and address of driver, name and address of registered owner of the vehicle, and upon request and if available show operator's license; failure to furnish aid, if requested or required.

To prove a case of felony hit and run, therefore, it is necessary to prove each of the foregoing elements. It must be shown that a driven vehicle was involved in an accident in which someone was injured or killed, and that the driver had knowledge of the accident. Knowledge of the injury or death is not necessary. It must be proved that the driver either failed to stop or identify himself, or offer aid if it was necessary or requested. The driver may stop or return to the scene, but unless he identifies himself the elements of the crime still exist. The investigator may prove knowledge, identity, and the offense by means of witnesses or entirely by circumstantial evidence. The owner of the vehicle, as a passenger, may be equally as guilty as the driver if he makes no attempt to stop at the scene and comply with the hit and run statute. The owner, under these circumstances, may be convicted of hit and run driving. Actual collision or contact between the vehicles involved is not necessary. "Involved in" is given the broader construction so that physical contact is not required. However, the driver involved must have committed the violation that caused the accident if there is no physical contact.

Time is important in hit and run investigation. The longer it takes to locate the driver the more time he will have to repair damage, destroy evidence, and establish an alibi. Therefore, the investigator faced with a hit and run investigation should get information on the air for the benefit of radio-equipped units as quickly as possible so that a wide search for the violator may be instituted at once.

Procedure at the scene of a hit and run investigation should be keyed to this need. A check should be made, first for injuries, then to be sure that the drivers of all vehicles involved are present. As soon as it is determined it is a hit and run, a description of the responsible vehicle, the driver and occupants, direction of travel, area of possible damage, and probable paint transfers should be obtained. The names of witnesses should be secured and the preliminary information broadcast as soon as possible in order that a minimum amount of time is lost in launching the search.

SELECTING A CHAIRMAN

If a committee is to be the vehicle for curriculum study, one of the most important factors to consider is the choice of a chairman.

The Administrator as Chairman

Sometimes a school administrator or supervisor--e.g., the assistant superintendent, a principal, curriculum coordinator, elementary supervisor, department chairman, or vice-principal--is asked to serve as chairman of the curriculum study committee.

Such an appointment is usually based upon the premise that curriculum work needs the immediate attention and direction of the administrator, who feels his responsibility for the program and wants his staff to know that he has a sincere concern for the curriculum.

The plan has some possible disadvantages. Sometimes, where the administrator acts as the chairman, the committee attempts to learn what the administrator wants the findings to be, and works in that direction regardless of their own personal feelings. Service on the committee may become more a matter of duty than real interest on the part of the teacher. Or, the administrator, burdened by many other responsibilities, neglects the work of the committee, fails to call meetings, and in the end stymies real progress or interest.

The Classroom Teacher as Chairman

Sometimes a classroom teacher acts as chairman. The administrator may hope through this plan to deliberately give teachers freedom in this area. He may wish to develop leadership among teachers and encourage teachers to assume greater responsibility for the direction of curriculum.

When the administrator, however, clings too closely to a "hands-off" policy, teachers often feel uncertain, especially if the administrator does not attend meetings. Members may not be sure that their recommendations will be supported, or that they are definitely working within overall school philosophy and program.

The Co-Chairmanship

Another possible plan is the co-chairmanship--with a classroom teacher and an administrator sharing the status leadership.

Once the committee is organized, and the administrative phases arranged, the administrator can step into the background, permitting the teacher to work closely with fellow teachers, while having the continuing interest and support of the administrator as a fellow committee member. Even when it is necessary for the administrator to give his attention to other matters, the committee can operate effectively.

A potential disadvantage of this plan is that the two leaders may fail to plan together, and the committee thus may have two heads leading in different directions.

In Any Case

Chairman or co-chairman, as the case may be, the role calls for one who can relate warmly and effectively with the committee. He must know the strengths of each committee member and be able to guide the application of these talents wisely.

His is the delicate task of balancing freedom and respect for the individual with responsibility for group progress--the challenge of helping each committee member to take increasing responsibility for his own development and that of the group.

2143

Having arranged for this immediate lookout to be broadcast, the investigator should question the witnesses fully. He should get their complete story and determine the amount of damage and injury. If there was a collision, how did the witness know? If a license number was obtained, how was it obtained and by whom? It is essential to maintain a chain of continuity of all evidence so the case will not break down in court.

The investigator should determine whether or not the suspect stopped at any time. If he did, did he converse with anybody? Any conversation should be recorded in the exact words, if possible, as an aid in questioning the suspect. Was any identification offered? Did the victim ask for any? The witness should be questioned as to whether he would be able to identify the driver. The best possible description of the driver should be obtained, as well as of the passengers. An accurate description of the vehicle should be requested, including the damage, make, model, year, color, and anything unusual or outstanding about the car. This should be as complete as the witness or witnesses can make it and supplemented by physical evidence the investigator discovers. Any new developments should be furnished the radio dispatcher so that other units may be advised.

It should be determined whether or not the witness actually saw the accident. A person who did not see the accident itself might have seen the damaged vehicle leave the scene. Persons working in nearby areas, or motorists arriving from the direction of the suspect's flight might come under this category.

No detail should be overlooked. If there was an injury, was it apparent? Did the suspect make any attempt to assist the victim? Was the victim conscious? How long from the time of the accident was it before the investigator arrived? Were there other violations on the part of the suspect such as excessive speed or driving while intoxicated? This is a two-fold investigation, and no particle of evidence should be overlooked.

The scene should be literally combed for physical evidence. Extremely small parts broken from the suspect's car may be matched with the vehicle to make a positive identification. Paint transfers or chips may be discovered. Clothing should be preserved to be analyzed, using great care not to handle clothing unnecessarily or roughly as paint is invisible to the naked eye in many cases and might be lost. The clothing of persons killed should be obtained from the coroner. In auto-pedestrian cases clothing should be analyzed whenever possible. Chain of possession should be maintained,

21696

and clothing should be handled as little as possible and properly marked for identification.

A thorough canvass of the area should be made for witnesses. Women make good witnesses in describing clothes, and boys in their early teens and younger will probably be accurate in determining makes of vehicles. The investigator should be alert for the return of the responsible driver to the scene of the accident. Mingling with the crowd, even going so far as to follow the officer closely, the driver may attempt to ascertain the progress of the investigation. The inquisitive person who displays an unusual interest might well be the wanted driver discovering how close the investigation is coming to him, possibly going so far as to destroy evidence.

Photographs of the accident scene, victim and vehicle should be taken, and other evidence photos obtained as indicated by the circumstances.

Throughout the investigation pertinent information should be given to the radio dispatcher as soon as obtained to aid other units in the search.

Follow-up activity will include checking garages, wrecking establishments, service stations and repair shops, and putting them on the alert for the wanted vehicle. Many other channels of group activity will be followed by other members of the department, as well as the investigator.

Should no apprehension of the suspect result, the investigator should revisit the scene periodically at the same time of day, day of the week, and date of the month. Through this pattern he may discover route salesmen, delivery drivers, or others who have a regular routine and may have been witnesses to the accident.

Once the vehicle is located and identification established, the driver will have to be found and connected to the crime.

When located, the approach should be positive. The suspect may spontaneously make a statement which will identify him as the driver involved. However, officers must remember to properly admonish the suspect.

Hit and run investigation and apprehension is one of the most difficult and interesting jobs of the investigator. There is no apparent motive. The driver may have acted spontaneously through fear or nervousness to avoid apprehension because of being intoxicated, unlicensed, with "the other woman", uninsured, or wanted for another crime.

CHAPTER 4

DETERMINATION OF SPEED FROM SKIDMARKS

In many investigations knowing the initial speed of the accident vehicle is of great value to the investigator. Drivers may not admit accurate speeds. Often the speed estimate of witnesses will be unreliable or disbelieved due to their unfamiliarity with speed and its results. A scientific method which eliminates much of the guesswork is that of computing minimum initial speeds from the measured length of skidmarks.

Excessive speed is a common accident cause. When faced with an emergency a driver will usually apply the brakes with maximum force or swerve the vehicle sharply. The resultant skidmarks provide evidence which serves as a basis for computing the minimum initial speed of the vehicle with reasonable accuracy.

Not only will this evidence be of assistance in prosecuting violators, but it may also serve to exonerate drivers who might otherwise be charged. A skid of 20 feet from 20 miles per hour does not mean that a skid of 100 feet, or five time times as long, indicates five times as much speed. The actual speed in this case would be only about 45 miles per hour.

This type of evidence is particularly valuable in auto-pedestrian cases where little damage is done to the vehicle. Where extensive damage results, all that can be measured is the amount of speed the vehicle lost in sliding. Energy absorbed in the collision is above and beyond that figure.

With emergency stopping, rotation of the wheels ceases almost instantly and wheels are said to be "locked." Locking the wheels will not stop the vehicle at once. Instead, the tires will slide upon the surface until all the kinetic energy of the vehicle has been transformed into heat energy, represented by the sliding of the tires. Since, by the law of conservation of energy, energy cannot be created or destroyed, the energy of motion must be equal to the energy of stopping.

While this energy transformation is taking place, a heavy deposit of rubber will be left on the pavement. This can be readily identified, and the length of the skidmark left by each wheel can be measured.

Coefficient of friction is defined as the ratio of force required to slide an object over a surface to the force (usually the weight) pressing the object against the surface.

21701

The force created by locking the wheels of a moving vehicle is the same as that necessary to drag the vehicle were its wheels locked. The coefficient of friction (also called the drag factor) formula is $f = \frac{F}{W}$ For example, if a force of 3,000 pounds were necessary to move a 4,000 pound vehicle with locked wheels, the coefficient of friction would be 75%.

$$f = \frac{F}{W} = \frac{3,000}{4,000} = 75\%$$

If the same vehicle were moving and the wheels were locked, a 3,000 pound force would "pull" on the vehicle until it stopped.

On dry, hard road surfaces braking forces which can be developed are fairly uniform. The coefficient of friction will vary slightly with changes in speed. In contrast, on wet surfaces, due to the lubricating effect of the water and other factors, the coefficient of friction will vary with different initial speeds. Therefore, use of the formulas for computing speed from skidmarks should generally be confined to dry pavements.

Even with a freely rolling wheel minute particles of rubber are being deposited on the surface of the pavement. However, these deposits are so small that no clearly defined markings are visible. With a heavy brake application it is often difficult to detect any markings on the pavement if the wheels continue to rotate. Under emergency conditions, however, maximum braking force generally causes the wheels of the vehicle to lock. On dry pavement the locked wheels will leave a heavy deposit of rubber which can be accurately assessed as to length, location, direction, and number of wheels affected.

When a heavy braking force is exerted the retarding force is greatest just before the wheels are locked. This type of tire marking is termed "impending". The wheels are just about to cease rotating, and usually the tire marks are less visible than those made by locked wheels. In some instances it is possible to see the design of the tire tread in the impending markings. Usually this type of mark leads directly to the locked wheel markings.

A general characteristic of the locked wheel type of markings is that the path of the vehicle is straight. This is true because it is impossible to change direction by steering once the wheels are locked.

21702

In many collisions there may be a sudden and violent change of direction due to impact with another vehicle or object. This change is usually visible, but many times results in a confusion of tire markings which are difficult to describe accurately.

In some instances, an abrupt change of direction is effected by the operator attempting to turn the vehicle from its path. It is possible when this occurs that clearly defined tire markings will be visible and that braking may or may not be in effect. In this case, a new force has been added to the vehicle which is described as "centrifugal force". This new force resists the change of direction which the operator is attempting to impart by turning the wheels.

Investigators should be aware that it is possible to leave tire markings on the pavement which closely resemble "locked wheel" or "impending" marks without any brake application. Such markings are many times identified by a variety of terms which are confusing. These types of descriptions do not lend themselves to intelligent interpretations or evaluations in reconstructing the facts of the collision.

In order to rectify this situation, a uniform terminology must be developed and used. To arrive at a conclusion as to speed based upon the evidence left on the roadway, it is necessary that all deceleration factors be considered. The primary deceleration factor is the braking mechanism. Secondary factors are the surface upon which the vehicle is traveling, its grade percentage, and its condition.

First among the uniform definition of skid mark terminology is that of a tire skid mark, defined as a mark left by a tire due to the sliding of the tire over a surface. Visible tire skid marks are made in three ways: EXTREME DECELERATION, EXTREME CHANGE OF DIRECTION, and EXTREME ACCELERATION.

Extreme deceleration: When the braking system is sufficient to cause the wheels to cease rotating they will lock and skid marks will be left on the surface. Even when the wheels are still turning, but are about to cease rotating, skid marks will be visible.

Extreme change of direction: This action may result from effort on the part of the operator or an impact. The resulting skid marks are usually visible to the investigator.

Extreme acceleration: This condition occurs when a propelling force exceeding the pavement efficiency is generated. If the driving force applied to the rear wheels is such that it will cause the wheels to "spin," skid marks will result.

The following basic terms have been adopted and will be used throughout this discussion as defining the various types of tire skid marks:

1. IMPENDING skid mark: left by a braked wheel rotating slower than the forward motion of the vehicle in a straight or curved line.

2. LOCKED WHEEL skid mark: left by a non-rotating wheel of a vehicle moving in a straight or curved line in the original direction of motion.

3. SIDE SKID mark: left by a locked, braked, or rotating wheel of a vehicle sliding in other than a forward direction, except when caused by centrifugal force.

4. CENTRIFUGAL skid mark: left by a rotating wheel of a vehicle rounding a curve or turning at such a speed that centrifugal force entirely or partially overcomes the frictional resistance between roadway and tire.

There are descriptive terms which can be used to describe skid marks after the basic term has been used. These may be "intermittent" to describe markings which are not continuous; " dual wheel," "single vehicle," etc., to indicate the number of wheels affected and the type of equipment; "curving," "straight line," etc., to describe direction and type. Any term which further describes the skid marks after the basic terminology has been used, and which can be employed to clarify the facts of the collision, is acceptable.

Only when the basic terminlogy is used by all investigators will it be possible to reach a common understanding. Thus, definite conclusions may be determined concerning speed, direction of travel, and point of impact from the skid marks at the accident scene.

In order that such evidence may prove of value in determining minimum initial speeds and to assure its acceptance by the courts, it is imperative that it be properly obtained and recorded. The investigator is concerned with how far the vehicle skidded. Therefore, it is necessary to measure the mark left by each tire of the vehicle. In some cases this is fairly easy to do; in other instances it is almost impossible when the marks of front and rear wheels are superimposed. In the latter case, the investigator must measure the total length of the skid mark and deduct the wheel base of the vehicle. In any event, he must establish that the marks were left by a certain vehicle. This is usually accomplished by an admission from the driver, the testimony of a witness, or the wheels of the vehicle being atop each skid mark when at rest.

In measuring curved skids (other than centrifugal skids) the tape should follow the curvature of the skid mark, as the distance the wheels were in contact with the road surface is needed to calculate for speed. The investigator must see both ends of the tape in order that his testimony will be admissible.

Sometimes a locked wheel will bounce and leave a "skip skid" - a series of locked wheel skid marks with short spaces between them where the wheel was in the air. In these cases the distances during which the wheel was not in contact with the road surface should be included in the skid measurement. Although none of the speed is being dissipated while the wheel is in the air, the greater energy dissipated before the wheel leaves the road compensates for this. The skips will be only a few feet long.

In some instances a person will apply brakes when faced with an apparent danger, leaving skid marks, release them as the situation changes, then apply them again - or the driver may "pump" the brakes. The skid marks will have a gap between them, but the gap will generally be more than ten feet in length. Each set of marks should be measured, added, and their total used for speed computation (the gaps are not included as is the case with skip skids).

Having measured the skid marks, the measurements must be properly recorded to be useful. For each wheel the length of the impending and locked wheel skids should be separately listed. It is also necessary to record the weather, the condition and the type of pavement, and the percentage of grade (noting whether it is up or down).

When this information is secured and preserved it is simple to calculate the minimum initial speed of the vehicle. This can be done in several ways. What the investigator must remember is that skid marks do not show all of the speed. Neither the energy used in braking before the wheels began to leave visible marks nor the energy left in the vehicle at the time of the collision will appear. What can be determined is the amount of speed lost in the distance the vehicle slid. The calculation will show less speed than the actual speed of the vehicle. Any deviation from the actual speed will, therefore, be in favor of the driver.

The simplest way to estimate the minimum initial speed of a vehicle traveling on a dry, level, hard surfaced pavement is to arbitrarily assign a coefficient of friction of 60%. This is a safe minimum. The percentage of grade is added to this figure if uphill or subtracted if downhill. Skids (impending plus locked wheel) from all skidding wheels should be averaged and the result used to calculate the vehicle's speed.

The formula used in calculating speed from skid marks is:

$$S = \frac{V^2}{30f}$$

"S" represents the skid distance in feet, "V" the speed in miles per hour, and "f" the coefficient of friction. This formula may be transposed to read $V^2=30Sf$ or $V = \sqrt{30Sf}$, which are easier to use. What the investigator is concerned with is the speed. He simply substitutes known factors in the righthand side of the equation, performs the multiplications, extracts the square root, and he has the minimum speed. This can be easily done in a matter of a few seconds at the accident scene and gives him a result close enough to guide his investigation. It is a quick method of determining whether there was sufficient speed involved to warrant running test skids or further analysis.

If there is indication of excessive speed, particularly in a serious accident, test skids should be made to assure that the evidence will be as good as possible in the event of prosecution. Although it is true that the weight of the vehicle involved, the condition of tires, or the condition of brakes (provided they are sufficient to lock the wheels) are not significant, the task of convincing a jury is much simpler if test skids are made by the same vehicle which was involved in the accident. In some cases damage may prevent its use; however, if possible the vehicle involved should be used. The tests should be made at the same location and in the same direction the accident vehicle was traveling. A minimum of three test skids from the same speed should be made and the longest skid mark used. Great care should be used in running test skids due to the danger involved. For all practical purposes, 30 miles per hour should be fast enough.

To compute speed from skidmarks it is necessary to know how to extract square roots. To find the square root of a number:

Step 1. Begin at the decimal and group digits to the left and right in pairs. The first "group" will be a single digit if the number has an odd count of digits; the first group will be a pair of digits if the number has an even digit count.

Odd digit number --12345.00

Grouped in pairs - 1 23 45. 00

Even digit number - 1234.00

Grouped in pairs - 12 34. 00

CHOOSING AND ORIENTING A COMMITTEE

Who should serve on the curriculum development committee? Although there is no universal answer to this question, it seems certain that the size of the committee should depend upon the coordinating time available, the nature of the problem, and the number of schools involved.

Surely an important factor will be provision for a wide variety of skills and abilities, a combination of experienced and inexperienced teachers, and a number of teachers who are held in high esteem by the faculty in general.

A large committee may be more representative of the total faculty, but the advantage of a smaller committee which can work more efficiently should be kept in mind. If true group consensus is to be sought through face-to-face discussion, the committee should be no larger than from twelve to fifteen.

Should teachers be chosen from one building, or from all buildings in a district? This depends in part upon those whom the problem will affect. Commonly esprit de corps is high and communication and transportation problems are minimized when the committee comes from one building. But district morale and articulation may be better served by an inter-building committee.

Should the committee be chosen on a voluntary basis or by formal appointment? The answer may well be a little of each. An all-volunteer committee is excellent if it has the balance of competence that is needed. If not, the administrator should be ready to ask others to contribute.

Is a standing or temporary committee better? This again depends on the problem or problems facing the committee.

How important is the committee members' orientation? However the committee is formed, there are two things its members must come to believe: (1) that what they are doing is meaningful and worthwhile, and (2) that the results will have an excellent chance for incorporation into school practice.

To make sure that these beliefs will foster real commitment to the work of the committee, the appointing authority must pay great attention to the orientation of the committee.

A painstaking preparation for the initial orientation of participants in curriculum study cannot be overstressed. The status leader responsible for getting the committee underway has very definite questions that he should be prepared to answer. Many such questions involve careful clearance with the rest of the administration and the board.

The checklist that is provided on the following page may guide the local leadership in planning for committee orientation.

What preparation is needed for the first committee meeting with the consultant? The administration has the responsibility for setting the scene for such a meeting. The committee should be aware of the forthcoming visit of the consultant so that he may be properly welcomed at the time of the meeting.

The reasons for inviting a consultant into the school should be clear to staff members. The consultant's background and special talents and experiences should be outlined when the introduction of the consultant is made to staff. Such information will tend to build respect and rapport in the eyes of those with whom the consultant is to work.

2144

Step 2. Find the largest digit which, when squared, will be equal to or less than the first group.

Odd digit number--

```
     1
  ┌──────────
  │1 23 45. 00
  │1
  │─
```

Even digit number--

```
     3
  ┌──────────
  │12 34. 00
  │ 9
  │──
```

Step 3. Subtract the square from the first group and bring down the next group.

Odd digit number--

```
     1
  ┌──────────
  │1 23 45. 00
  │1
  │─
  │0 23
```

Even digit number--

```
     3
  ┌──────────
  │12 34. 00
  │ 9
  │──
  │ 3 34
```

Step 4. Double the digit above the horizontal line, then place the product on line with and to the left of the difference determined in Step 2.

Odd digit number--

```
     1
  ┌──────────
  │1 23 45. 00
  │1
2 │─
  │0 23
```

Even digit number--

```
     3
  ┌──────────
  │12 34. 00
  │ 9
6 │──
  │ 3 34
```

21707

Step 5. Find the digit which, when placed to the right of the doubled figure and multiplied by the digit discovered, gives a product not in excess of the difference with its new group. Multiply, place the product below the difference, and subtract.

Odd digit number--

```
        1  1
      ------------
      | 1 23 45. 00
      | 1
   21 | 0 23
      |   21
      |    2
```

Even digit number--

```
        3  5
      ------------
      | 12 34. 00
      |  9
   65 |  3 34
      |  3 25
      |     9
```

Step 6. Repeat Step 5 (doubling figure above horizontal line, etc.) until desired decimal accuracy is achieved.

Odd digit number--

```
                1  1  1.  1  0  8
              ----------------------
              | 1 23 45. 00 00 00
              | 1
        21    | 0 23
              |   21
       221    |    2 45
              |    2 21
      2221    |      24 00
              |      22 21
    (22220)   |       1 79 00 00
    222208    |       1 77 76 64
              |           1 23 36
```

21708

Even digit number--

```
                 3  5.  1  2  8
              ┌──────────────────
              │ 12 34. 00 00 00
              │ 9
              │ 3 34
   65         │ 3 25
              │    9  00
  701         │    7  01
              │    1  99 00
 7022         │    1  40 44
              │       58 56 00
70248         │       56 19 84
              │        2 36 16
```

Step 7. Round off the result and check by squaring.

Odd digit number--

```
      111.11
      111.11
      111 11
     1111 1
    11111
   11111
  11111
  12345.43 21
```

Even digit number--

```
      35.13
      35.13
      10539
      3513
    17565
   10539
   1234.1169
```

As an example of the use of skid marks in determining initial speeds, the following will illustrate several principles: The investigator has measured 50 feet of accident skid marks, locked wheel plus impending, on a dry, level asphaltic concrete pavement. The driver involved states he was going 20 to 25 miles per hour. The quick method of estimating initial minimum speed is $V^2 = 30 \times 50 \times .60$, or 900. The square root of 900 is 30. Therefore, the minimum speed is 30 miles per hour. This can be done simply and without a test skid by arbitrarily assigning a 60 per cent coefficient of friction.

21709

Desiring to arrive at a true coefficient of friction, the investigator will run three test skids from the admitted speed of 25 miles per hour. These tests give skid distances of 28, 29, and 30 feet respectively. The longest skid from the claimed speed is 20 feet shorter than the accident skid. This should be quite convincing to the driver that he was traveling faster than he admits, particularly if the investigator points out the discrepancy in the skidding distance.

Results of the test skids may be used in three different ways. One of these is by means of a skid-speed chart, CHP Form 185, as illustrated.

21710

The investigator notes the necessary information, records his test skids, and arrives directly at the minimum speed of the accident vehicle by the following method:

Step 1

On the "Skid Distance in Feet" axis he plots the longest test skid, in the above instance 30 feet.

Step 2

On the "Speed in M.P.H." axis of the chart he runs a line up at 25 miles per hour, which was the test speed.

Step 3

These lines intersect at the broken line indicating 70 per cent coefficient of friction.

Step 4

The investigator then, using the same steps as indicated above, plots the 50 feet of accident skid on the "Skid Distance in Feet" axis. From the point where this line intersects the 70% "Coefficient of Friction" line, he draws a line to the "Speed in M.P.H." axis and read a minimum speed of 32 miles per hour.

21711

In the absence of a skid chart, the problem could be worked out by substituting known values in the equation for determining the coefficient of friction, $f = \frac{V^2}{30S}$, then substituting this in the $V^2 = 30 \times S \times f$ equation and solving for the unknown speed. This will give a minimum speed of 32 miles per hour.

A method which saves one operation is by direct substitution in the formula $V_a = V_t \frac{S_a}{S_t}$, where V_a equals accident speed, V_t equals test speed, S_a equals accident skid distance, and S_t equals test skid distance. This, too, gives a result of 32 miles per hour.

It can be seen by the above that the quick approximation with the assumed coefficient of friction of 60 per cent gives a result close enough for practical use.

In using a test skid, it is important that every effort be made to get all the impending skid; otherwise the value of the coefficient of friction obtained will be too high. It is necessary that the speedometer be accurate so that the evidence obtained will be reliable for presentation in court.

While the investigator will be able to calculate initial speeds closely by these methods, presentation in court will probably require expert testimony, including explanation of the various physical laws and mathematical formulas involved.

The expert will rely on the information given him by the investigator to reach his conclusion. This information must be accurate, understandable, and complete, for without this information skid mark evidence will be of little value. With the proper measuring and recording of skid mark evidence accurate minimum initial speeds may be computed.

In complicated cases where not all the wheels slide, or where the skid marks are on different types of surfaces, it will probably be up to the expert to determine if any use can be made of the skid mark evidence. However, it is important to record the evidence so that the expert may decide to what extent it is usable.

When a vehicle is rounding a curve there are two opposed forces acting upon it. Centrifugal force acts to keep the vehicle moving in a straight line, while centripetal force is being applied to turn the vehicle. If the centrifugal force is greater than the frictional resistance between the tires and the pavement, the vehicle will skid. Skid marks left by a vehicle sliding on a curve can be used to tell

something about how fast a vehicle was going, for centrifugal force is directly proportional to the weight of a body and the square of the velocity and is inversely proportional to the radius of the curvature of its path. The speed at which a curve can be rounded without skidding is known as the CRITICAL SPEED. When a vehicle skids on a curve without brake application it is because the critical speed was exceeded. By calculating the critical speed of a curve the investigator will know the minimum speed at which the vehicle must have been traveling in order to slide.

To calculate the critical speed for a curve, the investigator must know the RADIUS of the curve, the bank or SUPER-ELEVATION, and the COEFFICIENT OF FRICTION.

The radius of a curve is determined as follows:

1. Mark two points on the curve using the center line or outside edge. The points used can be where the curve straightens or two points 100 feet or less apart near the accident.

2. Measure the distance between these marks. The distance measured is called the chord. It is "C" in the formula below.

3. Divide the length of the chord by two, and without moving the tape find the middle of the chord.

4. Measure the shortest distance from the middle of the chord to the curve. Use a pocket tape if available. Measure to the nearest half inch. This distance is called the middle ordinate. It is "M" in the formula below.

   Example: Measure straight across part of a circular curve with a chord of 50 feet, "C." The distance from the middle of the chord (at 25 feet), to the curve is one foot. This is the middle ordinate, "M." Using these figures in either of the two formulas for determining radius:

   $$\text{Radius} = \frac{C^2}{8M} + \frac{M}{2}$$ (in this formula the middle ordinate is in feet)

   $$\text{Radius} = \frac{50 \times 50}{8 \times 1} + \frac{1}{2} = \frac{2500}{8} + \frac{1}{2} = 312.5 + 0.5 = 313 \text{ feet}$$

OR

$$\text{Radius} = \frac{3C^2}{2M} + \frac{M}{24}$$ (in this formula the middle ordinate is in inches)

$$\text{Radius} = \frac{3 \times 2500}{2 \times 12} + \frac{12}{24}$$

$$= 7500 + \frac{1}{2}$$

$$= 312.5 + 0.5 = 313 \text{ feet}$$

It is easier to use a calculator which works the formula. The radius of the circle (of which the measured curve is a part) is determined by drawing a straight line across the chart through the two known points - length of chord and middle ordinate. The radius is read at the point at which the line crosses the radius scale.

On the following page use the same measurements as in the previous example; chord 50 feet and middle ordinate 1 foot. Find the chord, 50, on the left scale, C. Find the middle ordinate, one foot, on the middle scale, M. Draw a straight line from the 50 on scale C through 1 on scale h to scale R. Read the radius on scale R at this point. It is 313 feet.

This same formula and calculator can also be used to find the radius of a small circle by using inches instead of feet for measurements. This might help find the size of a round headlight lens from a piece of glass found at the scene of an accident.

21714

Coefficient of friction may be determined as previously described. Superelevation is added or subtracted just as grade percentage is in other skid mark problems. (If test skids are made, the superelevation or grade is already included in the resultant coefficient of friction.)

Superelevation or grade percentage means the steepness of the road banking or a hill. They are both measured by the number of feet the road rises for each foot of level distance along or across the road. The resulting number is less than 1.00, and except on steep hills or banks, is less than 0.10.

When drawing a diagram of an accident scene, always draw an arrow pointing uphill after the grade number. Also, since uphill is plus grade, put the plus sign (+) in front of the number.

If the slope is uphill, it is a positive grade, and a plus sign (+) is written in front of the number. Downhill or negative grades are written with a minus sign (-) in front of the number. Whether a grade is positive or negative depends upon the direction of travel.

The grade or slope of a road is the rise divided by the level distance. The bank or superelevation is the same thing across the road.

The number representing grade is often mentioned in terms of feet of rise or fall per hundred feet of horizontal distance. It then becomes feet per hundred of grade, or per cent grade.

Example: A road rises two feet in a level distance of 50 feet. Divide 2 by 50. The result is 0.04. (This is 4 feet per hundred, or a 4% grade.) This information would be indicated on a diagram by an arrow pointing uphill and

21716

writing + 0.04 grade. This percentage of grade would be added to the coefficient of friction when computing speed from skid marks.

The formula to calculate critical speed is $V^2 = 15 \times R \times f$, or $V = \sqrt{15Rf}$, where V equals speed, R equals radius, and f is the coefficient of friction.

> Example: Calculate critical speed where the chord measures 50' the middle ordinate is 11", the coefficient of friction is 68%, and the superelevation is 2%.
>
> $R = \frac{3 \times 2500}{22} + \frac{11}{24} = 341$ feet.
>
> $f = .68 + .02 = .70$
>
> $V^2 = 15 \times 341 \times .70$
>
> $V = \sqrt{3580.50}$
>
> F = 59.8 mph (See illustrated page 2 of speed-skid chart.)

Where brakes are applied during a centrifugal skid the formula will not hold true, however, as brake application will cause skidding at lower speeds than if brakes were not applied.

The same formula used to calculate the critical speed of a curve is used to compute minimum initial speed from centrifugal skid marks. The centrifugal skid mark is the curve on which the chord and middle ordinate are measured. The radius of the curve of the centrifugal skid is entered into the formula and the initial speed calculated.

AN ORIENTATION CHECKLIST

This is a school administrator's checklist for providing orientation for teachers who will be participating in a curriculum improvement project. It might be used as a discussion guide at an early meeting of a committee.

Do all who are involved understand the following with relation to the proposed project?

_____1. Long range goals? What are the possibilities for the years ahead?

_____2. Short range goals? What are some reasonable expectations for this semester or year?

_____3. Approach? Is the focus of change on the improvement of classroom instruction?

_____4. Functions? What is the exact nature of the committee's job? What is the committee's authority? What is its relation to other committees or to school leaders?

_____5. Blocking possibilities? Who or what may possibly block or impede the committee's work?

_____6. Supporting efforts? What support is being developed for the committee--among school authorities, the public, other staff members, or elsewhere?

_____7. Communication lines? To whom does the committee report? Who else should be informed of committee progress?

_____8. Freedoms? With whom may the committee consult? Whom may the committee involve in its work?

_____9. Responsibilities? What deadlines must the committee meet? What obligations does it have?

_____10. Resources available? What may the committee expect in the way of secretarial, consultant, or other professional help? What materials for study, or instructional materials for experimentation? How much released time for committee work, visits, and conferences?

CRITERIA USED IN CHART DERIVATION

LAY OUT A 50 FT. CORD WITH A TIGHTLY DRAWN TAPE-MEASURE ACROSS THE ARC OF THE CENTRIFUGAL SKID MARK, THE DISTANCE FROM THE MIDDLE OF THE CORD, MEASURED ON A PERPENDICULAR TO THE TAPE AT 25 FT. TO THE OUTSIDE OF THE ARC, IS THE MIDDLE ORDINATE AND IS READ IN INCHES AND CONVERTED TO FEET.

TO FIND THE SPEED OF THE VEHICLE WHICH LEFT THE CENTRIFUGAL SKID MARKS, FIND FIGURE, ON THE CHART BELOW, CORRESPONDING TO THE MEASUREMENT OF THE MIDDLE ORDINATE; PROJECT A LINE HORIZONTALLY UNTIL IT INTERSECTS WITH THE DIAGONAL LINE FOR THE COEFFICIENT OF FRICTION FOR THE ROAD SURFACE; THEN PROJECT A LINE DOWN TO THE SCALE AT THE BOTTOM OF THE FORM AND READ THE SPEED IN MILES PER HOUR.

Handbook For School Bus Drivers

A Suggested Outline

It is important that all school bus drivers be familiar with school district rules and procedures relating to bus routes, maintenance, personnel policy, time schedules, and transportation policy. This can best be achieved through a pamphlet given to each driver for ready reference.

The following outline, compiled by the Division of Educational Management Services of the State Education Department, is intended to assist school administrators in the development of such a pamphlet. The outline points up the important areas of information which should be available to the school bus driver. Undoubtedly, each district will find that other important local information must be added.

The Division of Educational Management Services is ready to assist any school district that would like additional information and assistance.

RADIUS CALCULATOR

is especially important. During the fall and late spring, when the days are warm, the children often lower the bus windows. When a bus with lowered windows drives past brush, twigs on the brush slap along the side of the bus much as a stick will rattle down a picket fence. As the twigs rattle they vibrate faster and faster until parts of the limbs actually break off. These parts have been known to fly into the bus and injure students. Be especially cautious when operating a bus under these conditions.

(20) In parking the bus at the end of each run, be certain that it is positioned well off the roadway where it cannot become a hazard to other motorists. Don't expect them to know that the bus is not in use.

(21) Do not allow the bus to stand beside the road while you take a "coffee break." Better yet, take the break after you have stored the bus for the day.

c. Local Driving Rules

Because of the differences in the transportation patterns of various school districts, local driving regulations are often necessary. This portion of the handbook can describe any existing local driving rules.

OUTLINE - SCHOOL BUS DRIVERS' MANUAL

Part I - General Information

1. Directory of School Principals, Central Office Personnel, and Telephone Numbers

   a. This section should be placed at the front of the manual, with instructions as to conditions under which each listed person should be contacted. This will provide the driver with a ready reference for use in emergency.

2. School Transportation Philosophy and Policy

   a. A statement of the objectives of the transportation system will help familiarize the driver with the thinking of the administration and board of education regarding transportation philosophy.

   b. A clear statement of policy will help the driver understand the necessity for establishing distances from the school as a criterion for eligibility for transportation.

Part II -The School Bus Driver and His Daily Responsibilities

1. Specific Duties

   a. This section should include the daily work of the driver, presented in such a manner that there can be no doubt as to the routine duties he is to perform, and the times the work is to be performed.

2. Responsibility to the Board of Education

This section is reserved for a statement of general responsibilities the board may impose upon the driver as a condition of employment. Included are the following items:

a. To understand and honor the conditions of his employment

b. To take maximum precautions for the safety of the pupils placed in his care

c. To take good care of the equipment entrusted to him

d. To understand and support school policy

e. To assist in the establishment of desirable attributes in pupils

f. To heed all regulations relating to routing, schedules, loading, and unloading

g. To observe faithfully school requirements relating to transportation reports

h. To practice every practical economy so that maximum service may result

3. Responsibility to the (District) Superintendent

This section explains the powers and duties of the (district) superintendent of schools, and outlines the responsibilities of the driver to him. These responsibilities include:

a. To maintain desirable personal habits and moral standards

b. To recognize and respect the superintendent's authority

4. Responsibility to the Supervising Principal

Here may be enumerated the various responsibilities the driver owes to the supervising principal as executive officer of the board

of education. Among the responsibilities are:

a. To comply with the principal's requests

b. To recognize that all school employees are under the principal's supervision

c. To cooperate with the bus safety program

d. To report all matters of discipline, and to cooperate in the correction of them

e. To observe all regulations relating to routing and schedules as laid down by the principal

f. To conduct himself in a prudent manner

5. Responsibility to the Transportation Supervisor

Since the bus driver's closest relationship with the school administration is usually through the transportation supervisor, the driver must be fully aware of his responsibility to the supervisor. Some of the responsibilities are:

a. To recognize the authority of the transportation supervisor as the driver's immediate superior

b. To make all necessary reports in accordance with the supervisor's directions

c. To be available for work at the specified times

6. Emergency Procedures

a. Breakdown procedures

This portion of the manual would spell out specific action to be taken in the event of a breakdown of a vehicle on the road. Special weather and road conditions should be taken into account in preparing material to be presented here.

b. Accident Procedures

Each year a number of accidents involving school buses occur in this State. The driver should be aware of his responsibility and the exact procedure to be followed if he is involved in a traffic mishap. In this regard, there are certain basic rules which should be followed by the driver who is involved in an accident

(1) Stop immediately, quickly survey passengers

(2) Protect the scene; use flares, flags, etc.

(3) Render assistance to the injured. Send, don't go, for help

(4) Call police, local school authorities, if necessary

(5) Get names and addresses of witnesses and/or passengers

(6) Supply name, address, operator's license number and vehicle registration to proper authority

(7) Get similar information from other driver. Also, the name of his insurance carrier

(8) Get names and addresses of occupants of other vehicles

(9) Determine extent of injuries

(10) Make notes of damages to vehicles or property

(11) Refrain from trying to argue, place blame, make settlements

(12) Do not sign statements

CHOOSING A CONSULTANT

The choice of a consultant to work with a school on a curriculum problem can be very important to the success of the project. How should such an individual be selected to assure the proper person for the job?

Often a consultant is chosen on the basis of past reputation and experience in other situations. Usually such a background is quite helpful and accurate in predicting success. However, wherever possible the consultant and the school should hold a preliminary meeting to explore the problem that has to be studied. This meeting can be accomplished with no commitment on the part of either side. Such a meeting permits everyone to become acquainted and to establish an early rapport, or allows opportunity for both sides to withdraw, if expectations are not satisfied. Experience has shown that it is better to have such discoveries at the start, rather than at a later time when the situation becomes much more involved.

What should be recognized in this process is that success in one situation does not necessarily guarantee success in a similar one. Much of the success of the consultant in helping a school is dependent directly upon the rapport and faith he establishes over a period of time with the school personnel involved.

Some Cautions

It is the responsibility of the consultant to bring to the school the kinds of experience and training that are needed for the tasks to be accomplished. If this cannot be done, then the consultant should not accept the assignment. But there is another responsibility--this one on the part of the school. Quite often the success of the consultancy will depend upon how the school uses or misuses the consultant.

Some schools have made the mistake of expecting the consultant to act as the local committee chairman, or to play the same role as a staff member. But the consultant cannot act for the local chairman simply because it may be necessary for the chairman to continue to function with his committee in the interim periods between meetings with the consultant.

Even were it possible, it would certainly be unwise for the chairman to abdicate his leadership role in the curriculum process to an "outsider." For the consultant to take on the same role as a staff committee member would mean involvement in considerable minutiae resulting in waste of valuable consultancy time.

Other examples of the improper usage of a consultant by schools could be presented. The school that expects the consultant to have all the answers is surely in for disillusionment. The staff that looks to the consultant merely to confirm its already pre-conceived beliefs will no doubt be disappointed at the first honest disagreement of opinions. In short, a school needs to learn how to use the services of the consultant effectively, as much as the consultant needs to develop his skill.

Whether the school district is ready to work with a rather flexible, permissive type of consultant, or whether it needs a more aggressive or directive person, should be carefully considered in the selection process.

Possible Assistance

Helpful in the selection of a consultant may be membership in an area study council or curriculum association whose leaders are prepared to locate and nominate potential consultants with special skills.

2146

c. Accident Reporting

The reporting of accidents or mishaps in writing cannot be emphasized too strongly. In any given case, it may be necessary to report to one or more of the following agencies:

(1) Local authorities and school administration

(2) Commissioner of Motor Vehicles

(3) Public Service Commission

(4) State Education Department

When the accident involves personal injury, the driver should fill out MV-104 Forms, or some facsimile, for any injury to any passenger, no matter how trivial he may feel it is. (This could be such things as bumped knees, cut lips, or injury caused by falling on the stepwell of the bus).

In any case where the driver is unaware of such accidents, but has them brought to his attention by the school administration or parent, he should fill out the appropriate form, making a statement to the effect that he "was not aware of anything out of the ordinary happening" on the school bus that day. The driver has the obligation to tell the truth and not to report on what students think they saw.

The driver should immediately report all personal injuries to authorized personnel employed by the district.

A summary file of accident data should be kept by the transportation supervisor. This file will supply immediate

(1) Drivers shall be familiar with the Vehicle and Traffic Law, Regulations of the Commissioner of Motor Vehicles, and Regulations of the Commissioner of Education pertaining to pupil transportation.

(2) Drivers shall make a full stop at all railroad crossings and at State highways before crossing.

(3) Drivers shall give warning before making a left-hand or right-hand turn.

(4) Drivers shall not leave the school bus when children are inside except in case of emergency, and in such case before leaving the bus, the driver shall stop the motor, remove the ignition key, set the auxiliary brake, and leave the transmission in gear.

b. Defensive Driving

In addition to the Commissioner's Regulations, there are certain defensive driving practices which should be observed by all school bus drivers. These include the following:

(1) Safety is first, schedules are secondary. Safe driving takes precedence over all other considerations.

(2) Definition of a safe-defensive driver is one who is careful not to commit driving errors himself, who makes allowances for lack of skill or lack of proper attitudes on the part of other drivers, allows for weather and road conditions or the actions of pedestrians and other drivers to involve him in an accident. He keeps continually on the alert,

control to stop if necessary. Professional school bus drivers often come to complete stops at all rural road intersections. Before making a turn, make sure that no vehicle is approaching from the rear and that the turn can be made without interference with oncoming traffic or pedestrians. Use turn signals. Get into the proper lane for a turn.

(7) Be sure of clearance before attempting to pass, sound horn if needed, and check for clearance before returning to your proper lane. Use mirrors and turn signals when changing lanes.

(8) When following traffic, maintain a safe braking distance between your bus and the vehicle ahead for full assurance that you can stop, should the vehicle ahead make a sudden stop. There is no excuse for colliding with the vehicle ahead.

(9) When approaching a stop to pick up children, give a right turn signal when you are certain the move to the right can be done safely. Then turn to the right and establish your position in the correct stopping lane. Be sure to neutralize the right turn signal at this point. Pull to a stop, allowing plenty of room for unexpected actions of the children. There will never be any excuse for running over a child who is unexpectedly pushed in front of a school bus by others around him, or who suddenly makes

a move placing him in such danger. Allow every student to be seated before starting.

(10) When pulling onto the highway, check to make sure that the move can be done with safety. Give a left turn signal, then move out into traffic, neutralizing the left turn signal when you have established your position in the right hand lane of traffic.

(11) When stopping, aim high in traffic, check the passengers, and the traffic following in the rear view mirrors, before making a smooth stop. Make the stop in a manner so as not to endanger passengers or place the bus in danger of being struck in the rear by another vehicle.

(12) Be certain that all backing movements can be done with absolute safety. Be certain that there is no child behind the bus. Be certain there are no vehicles behind your bus in a place where you could back into them. Get a guide whenever possible. Eliminate backing on the school grounds.

(13) No bus shall be driven at a speed greater than is reasonable and prudent, having due regard for weather, traffic, and road conditions. A maximum route speed of 35 miles an hour is recommended. At a maximum speed of 35 miles an hour you will be able to complete your route in a reasonable time.

(14) Whenever passengers must stand while the bus is in operation, make certain that they move to the rear, and that none is standing ahead of the stanchion bars and the floor marking.

(15) All lights on a school bus must be in operating condition. Burned out or defective lights must be repaired before operating the school bus under conditions where these lights must be in operation.

(16) No passenger is to be permitted to board or alight while the bus is in motion. Doors must be kept closed while the bus is in motion.

(17) School bus operators should give pedestrains the right of way at all times.

(18) Make an effort to get a disabled bus out of the roadway and into a safe place where it is protected from further damage. It is recommended that emergency equipment, such as flares and flags, be displayed.

(19) When you have knowledge of road hazards, such as ruts, or holes in the roadway, dangerous bus stops, projecting objects such as tree limbs or leaning poles, make a report to your supervisor for investigation and correction. State road commissions, generally speaking, are responsible for clearing brush from roadways so that buses can operate without damage to the vehicle or injury to the passengers within the vehicle. With school buses this

recognizes an accident-producing situation far enough in advance to apply the necessary preventive action and concedes the right of way when necessary to prevent an accident.

(3) Brakes must be tested before operating the school bus. The bus must be operated within its mechanical limitations. If the brakes are inadequate for safe operation, park the bus off the road if possible, and immediately call the transportation supervisor. Better yet, don't start on a trip when the condition of the brakes is questionable.

(4) Windshields and mirrors are to be kept clean for clear visibility. Open the side window for proper ventilation if necessary, and report any defective defroster. Check heater hoses and hose clamps for leaks. Mirrors are to be properly adjusted. Report for repair any cracked or defective mirror. A hand cloth should be in every operator's kit.

(5) Smooth starts and smooth stops will prevent personal injuries and preserve equipment. Reduce speed over rough roads. Gears are to be meshed without clashing. The bus is to be held by the foot brake on any grade, and not by power.

(6) Avoiding collisions at intersections is the bus operator's responsibility. Approach at a prudent rate of speed, observe to right and left, and have bus under

d. Seasonal Driving Conditions

Some geographic locations and climatic conditions will require that drivers be provided with information regarding emergency procedures, such as controlling the vehicle in a skid. This section might be used for this purpose.

8. Maintenance and Sanitation

This section may spell out the specific responsibilities of the driver in inspection and maintenance of the buses. Also detailed here would be the specific duties of the driver in maintaining his bus in a clean and orderly condition.

Part III - The School Bus Driver - His Qualifications and Relationships

A. Driver Qualifications

1. Legal Requirements

Section 163 of the Regulations of the Commissioner of Education provides for certain minimum physical, license, age, and character requirements for school bus drivers.

a. Approval for employment of school bus drivers. Approval for employment of a school bus driver shall be in writing on a form prescribed by the Commissioner of Education.

b. Age. All drivers of school transportation conveyances shall be at least 21 years of age, but not in excess of 70 years of age.

c. Physical fitness

(1) Each driver of a school transportation conveyance shall meet the following basic minimum physical requirements:

(a) Minimum vision (with or without glasses) shall be 20/40 in each eye

(b) Shall have all limbs, hands and feet. In the case of fingers there shall be at least two fingers and the thumb on one hand and four fingers and the thumb on the other hand

(3) Personal Qualifications

Beyond the legal requirements and the regulations of the local school district, every school bus driver is expected to possess certain personal attributes which enable him to adequately perform his duties. Among these are:

(a) Reliability

(b) Ability to get along with others

(c) Freedom from undersirable language

(d) Sufficient initiative to handle unforeseen situations

(e) Moral conduct above reproach

(f) Ability to work within an organization

Other characteristics may be added as the board of education desires.

B. School Bus Driver Training

If some form of driver training is required as a prerequisite to employment or as a requirement for continuing employment, the driver should be made aware of this fact in this portion of the manual.

An explanation of the course content and the school bus driver training certificate might also be discussed.

CHECKLIST FOR CONSULTANTS

The following checklist is intended as a general guide for consultants for the preparation and conduct of initial meetings with school districts. All items do not apply in all situations.

Preparation Prior to Meetings

_____Read available materials on the proposed study topic.

_____Find out all you can about the district and its problems.

_____Accept the idea of beginning where the school district is.

_____Have a 20-minute speech ready in case it is requested.

_____Select, if possible, a book, a bibliography, or some material on the study topic to take to the local committee.

Preliminary Visit with Administrator and Local Chairman

_____Encourage them to state their goals and expectations.

_____Suggest goals or procedures as appropriate.

_____Find out how much leeway the curriculum development committee will have in operation.

_____If committee has not yet been chosen, discuss membership, expectations, and method of choosing committee.

_____Discuss role of the total faculty in the project.

_____Differentiate roles of local study chairman and consultant.

_____Discuss the best times for meetings and the possibilities of released time for teachers.

First Visit with Committee

_____Let the local study chairman preside.

_____Explore definition of the proposed study topic and sub-topics.

_____Elicit problems, as they see them, from all committee members.

_____Offer suggestions on experimentation or studies, either individual or group, for the committee.

_____Offer to help the committee locate important data which may be needed.

_____Discuss time arrangements for this work.

_____Discuss need for faculty involvement in the project.

_____Set time for the next meeting.

ABSTRACT - Developed by the Highway Users
Federation for Safety and Mobility, this
course syllabus will be useful in introducing
students to the broad spectrum of highway
transportation. Such a survey course is
intended for the community college level and
treats such topics as: (1) Police Traffic
Supervision, (2) Motor Vehicle Administration
and Traffic Accident Records Systems, (3)
Traffic Engineering, (4) Education and Public
Information, (5) Traffic Legislation and
Judicature, and (6) Health, Medical Care, and
Transportation of the Injured. Included in
the outline is an introductory synopsis,
educational objectives, and a rather
comprehensive list of references. (JS)

21747

NATURE AND SCOPE OF THE HIGHWAY TRANSPORTATION SYSTEM

I

COURSE PURPOSE

Intended for the community college student who will come from (1) government, business, and industrial groups engaged in some phase of traffic management, (2) students enrolled in some other fields, (3) students matriculating in college, but not yet decided on a specific career.

This course is designed to (1) improve the student's knowledge and understanding of the highway transportation system, (2) provide the student with a broad conceptual base as preparation for advanced and more specific learning.

Prerequisite: None

Catalog Description:

Nature and scope of the Highway Transportation System; a survey of the major functional areas and their inter-relationship.

(c) There shall be a good utilization of both arms and legs

(d) Hearing in each ear shall be adequate (without hearing aid)

(e) Shall not have any other physical or mental condition which might impede the ability to operate a bus safely

(2) Each regular and substitute school bus driver shall be examined by a physician prior to beginning service. Medical examination shall be reported by the physician on forms prescribed by the Commissioner of Education. Such physical examinations shall be conducted within two weeks prior to the beginning of service in each school year and shall be immediately reported to the superintendent of schools or district superintendent of schools. The physical examination shall include, as a minimum, those requirements specified on the prescribed Medical Examination Report. The report of the physician, in writing, shall be considered by the superintendent or district superintendent in determining the fitness of the driver to operate or continue to operate any transportation facilities used by pupils.

d. Required licenses. Each driver of a motor vehicle conveying school children shall have the appropriate operator's or chauffeur's license to operate such motor vehicle.

e. Character requirement. The driver of a vehicle for the transportation of school children shall be of good moral character and thoroughly reliable. At the time of initial application and at such other times as the superintendent of schools or district superintendent of schools may determine, each applicant for approval for employment as a school bus driver shall furnish to the superintendent at least three statements from three different persons who are not related, either by blood or marriage to the applicant, pertaining to the moral character and to the reliability of the applicant.

(2) Local Requirements

The requirements set forth by the Commissioner's Regulations constitute only minimum standards. A school district may establish more rigorous requirements if the board of education so desires. If such regulations exist, they should be detailed in this section of the handbook.

21740

C. Relationship to Parents and the Driving Public

The school bus driver is, in a sense, an important public relations agent for the school. His relationships with parents, pupils, and the public can influence sentiment toward the school for good or ill. Listed below are some examples of the kinds of material to include in this section.

1. Relationship to Parents

Parent cooperation is necessary in maintaining acceptable standards of education and discipline in the schools. The school bus driver can favorably impress parents by:

a. Adhering strictly to the time schedule

b. Observing strictly all traffic rules

c. Demonstrating a firm but friendly attitude toward pupil passengers. Other items may be added at the discretion of the individual school district

2. Relationship to the Driving Public

The motoring public is influenced in its attitude toward the school by the actions of the school bus driver. In order that these drivers be favorably impressed, the school bus driver should observe the following rules:

a. Obey all traffic signs, rules, and regulations

b. Use flashing red signal lamps only when receiving or discharging passengers

c. Be considerate

d. Don't lose your temper

Other items may be added at the discretion of the individual school district.

D. Relationship to Pupils

1. Driver Attitude

The attitude of the driver should be consistent with the three F's (firm, friendly, and fair). The good school bus driver is able to control the pupils without alienating them.

2. Characteristics of a Well-Disciplined Bus

a. The bus is clean and well kept

b. The pupils practice a proper amount of self restraint for their developmental stage

c. The bus driver adheres strictly to the schedule

d. The pupils themselves frown upon "horseplay"

e. The pupils enter and leave the bus in an orderly fashion

f. The pupils remain seated after entering and before leaving the bus

g. A friendly, but not intimate, feeling exists between the driver and the pupils, especially at the secondary level

h. Pupils refrain from thrusting their arms out of the windows and keep their legs out of the center aisle

i. The pupils hold conversations in a normal tone of voice so that driver distraction is kept to a minimum

j. The authority of the driver is accepted by the pupils

k. The rules of conduct are well established and there is a high degree of compliance on the part of the pupils

3. Rules to be Observed by Pupil Passengers

Section 163 of the Commissioner's Regulations prescribes certain basic rules for pupils riding buses. In addition to these, each school district will undoubtedly have certain regulations governing pupil conduct on buses. These rules should be listed here.

4. Acceptable Forms of Disciplinary Action

Although each school district will have its own procedures for handling cases of discipline, there are certain methods of correction which are forbidden to school bus drivers. These, as well as the acceptable disciplinary procedures, should be clearly spelled out in this section.

Part IV. Standard Forms and Their Use

A. This section explains forms which all bus drivers may be required to use. For example, a copy of the standard medical blank could be included, together with a statement that an annual physical examination is required within two weeks of the time that the driver begins service. Other forms to include are:

1. Accident reports
2. Daily reports
3. Application and renewal blanks
4. Other local reports required of drivers

II

COURSE OBJECTIVES

Activities during the course should be directed toward aiding the student to:

1. Acquire a knowledge of the manpower requirements of the system that will enable one to identify broad-field occupational opportunities.

2. Develop a recognition level of the functional areas in the system, and a concept of their interrelationship.

3. Realize the importance of having well qualified personnel in the system.

4. Become aware of the highway transportation system's contributions to society.

5. Distinguish the role of the (1) driver, (2) pedestrian, (3) vehicle, (4) and environment, in the system.

6. Become better informed as to the magnitude of the traffic problem, and the consequences of its continued growth.

7. Stimulate interest in professional literature related to highway transportation.

8. Recognize the contribution of modern technology to the highway transportation system.

9. Appreciate the value of a continuing education program for those persons working within the system or in a related enterprise.

10. Develop a concept of the highway transportation system as an essential element in the total transportation system.

CHAPTER IV

Maintaining Momentum

It takes much more than a good start to guarantee a successful venture. There is work to be done.

When a curriculum revision program is off the ground, the matters of management, continued careful planning, and communication become crucial.

Once the glamour of novelty wears thin, curriculum ventures become a real test of insight, human relations, and dedication. A responsible plan for curriculum improvement provides for the conservation of human resources.

This chapter is especially concerned with conditions under which human potential keeps growing. The big goal, of course, is morale. Morale grows when people grow. Morale is not complacency or even contentment; it demands a continuing challenge that teachers feel they have a reasonable chance to meet.

We emphasize the techniques of working with groups. Important references for further study on group process in curriculum development include Amidon (3), ASCD 1948 (5), Douglass (17), Fleming (18), Prestwood (26), Shane (27), and Thelen (30).

"Better not to preach the crusade than to neglect the crusaders."

4. Research can assist in the identification of conditions which tend to be associated with highway problems.

5. A characteristic of research is that answers to questions generally lead to new questions.

6. Disseminating research findings.

G. The universal utility of computerized data processing in the highway transportation system.

Listed below are just a few of the tasks performed by computers. The teacher may wish to equate these tasks and/or others with specific functions within the highway transportation system to illustrate the variety of application.

1. Information storage.

2. Performing calculations.

3. Communications

4. Programmed instructions.

5. Accounting

6. Mechanical analysis.

H. Highway transportation as an element of the total transportation system.

1. Operational relationship with air, rail, and water transportation.

2. The inter-dependent nature of the elements of the system.

I. The role of commercial highway transportation within the system.*

1. Contribution to the system.

2. Reliance upon the system.

3. Manpower requirements.

*The teacher may enhance (I) if the commercial manpower requirements of a particular community warrants. Additional development of this section

may be accomplished by relating each
ional areas listed under (J), with t
of the commercial highway transporta

J. Functional areas* of the highway tra
system and their inter-relationship.

1. Police traffic supervision.

2. Motor vehicle administration.

3. Traffic engineering.

4. Public education and information

5. Traffic legislation and judicatu

6. Health, medical care and transpo
the injured.

*These areas represent the major cla
be dealt with in this course. Ther
presentation at this time should be
identifying these areas as represent
which will follow, and; (2) establis

UNIT TWO

Police Traffic Supervision

A. Traffic direction and control.

1. Vital part of traffic policing.

2. The role in which the police make the most direct contact with the most people.

3. The increasing problem of keeping traffic moving efficiently and safely.

4. The changing character of the job. (Resulting from increased traffic volume and the complexities of street traffic movement.)

B. Traffic accident reporting and investigating.

1. Protection of life and property.

2. Observing and recording data that might be useful in determining how and why the accident happened.

3. The distinction between accident reporting and accident investigation.

4. Accident investigation data may be utilized by the courts, engineers, educators, and motor vehicle administrators in the administration of their responsibilities.

5. The utility of a coordinated accident record system. (Inter-departmental, inter-city, inter-county, inter-state.)

C. The role of enforcement.

1. The philosophy of traffic law enforcement.

2. Supervision of motor vehicle traffic is a major activity of all American police departments.

3. Effectiveness of enforcement is affected by; (1) legislation, (2) education, (3) highway and traffic engineering, (4) driver licensing, and (5) vehicle inspection.

4. The impact of enfo

III

COURSE TOPICS

Unit One	Introductory Synopsis
Unit Two	Police Traffic Supervision
Unit Three	Motor Vehicle Administration and Traffic Accident Records Systems.
Unit Four	Traffic Engineering
Unit Five.	Education and Public Information
Unit Six	Traffic Legislation and Judicature
Unit Seven	Health, Medical Care and Transportation of the Injured.

UNIT ONE

Introductory Synopsis

A. Historical perspective of the highway transportation system. (Include a brief review of the National Highway Safety Act of 1966.)

B. The function of the highway transportation system in contemporary society.

C. Manpower requirements of the system.

   1. Professionals

   2. Semi-professional technicians.

   3. Highly skilled technicians.

   4. Craftsmen and skilled tradesmen.

   5. Semi-skilled workers and operatives.

   6. Unskilled workers.

D. The need for increasing the competencies of personnel working in the highway transportation system.

E. Basic components of the system and the consequence of their inter-action.

   1. The driver.

   2. The vehicle.

   3. The environment.

F. Research: A vital element in each of the functional areas of the highway transportation system.

   1. Research is an orderly way of seeking answers to questions.

   2. Research is stated in terms of probability rather than certainty.

   3. The objective nature of research.

PROBLEMS OF COMMITTEES

Finding Time to Meet

Where do we get the time to do this extra work? This question will be in many teachers' minds. The answer is usually one of the following:

After school

Partly on school time, partly after school hours

On regular school time in the regular school day

As superintendents come to see curriculum work as a basic part of teaching and not as an extra, they often try to give the last answer, tending to accept the old adage: "No souls are saved after four o'clock."

But because released time means the possibility of added expense, and often a problem in obtaining suitable substitutes, the administrator may not be free to do what he would like to do. The problem of building community support for the idea of released time is one on which faculty committees can help by direct involvement of parents and citizens, especially those who exercise unusual influence in the community.

How Often To Meet?

The frequency of meetings should depend on the job to be done and the urgency of its completion. For committees meeting with a consultant, perhaps a two to three week interval is about right. Sub-committees might meet in between.

A good committee chairman does not try to complete everything in a bi-weekly or tri-weekly meeting, however. He plans for interim conferences with subcommittee chairmen, makes sure that reports are ready in advance, and tries to iron out personal problems before the meeting--problems that otherwise would derail the committee.

Careful Structuring

Most good meetings don't happen. They are very carefully structured.

What does this mean? It means that the chairman:

Plans carefully for the involvement of every committee member.

Builds in procedures for helping the members to identify more strongly with the committee.

Encourages very specific short-range targets for each member and sub-committee for the next meeting.

Briefs the consultant or other resource persons on the nature of the contribution desired of them. Prepares an advance agenda allotting tentative times for each item depending upon the degree to which discussion is really necessary.

The Chairman's Dilemma

In structuring a meeting the chairman faces the problem of whether his hand shall be too light or too heavy. If he plans the meeting too casually, hoping for a maximum of freedom of discussion, he may end up with a rambling, wandering meeting which has accomplished nothing. If he structures it too much, hoping for maximum efficiency in use of time, he may find he has railroaded through a program which has not been thoroughly considered by all.

The middle way is to prepare an agenda, but always consider it tentative. Abide by its time schedules unless the committee by deliberate action decides otherwise. As the agenda samples on the next pages illustrate, much can take place in a meeting, but rarely without the most intensive pre-planning.

Starr, Edward A. The Practice of Traffic Management. Dallas, Texas: Transportation Press, 1952.

UNIT FOUR

Traffic Engineering

A. The interdisciplinary nature of transportation engineering.

1. Highway engineering.

2. Vehicle engineering.

3. Traffic engineering.*

*Please note that the emphasis has been placed on traffic engineering in this course due to the fundamental interrelationship of the traffic core. However, the occupational opportunities are equally prevalent in highway engineering and vehicle engineering, and the prudent teacher will encourage the student to read from the related literature those publications common to these areas.

B. The philosophy of traffic engineering.

1. The basic function of traffic engineering.

2. Traffic engineering's role in the highway transportation system.

3. The correlation between efficient traffic movement and highway safety.

4. The importance of sound traffic operational controls.

C. Improved operations through traffic engineering.

1. Traffic engineering investigation of vehicle-flow.

2. Coordinated signal systems for continuous traffic flow.

3. Curb parking control.

4. The through-street plan.

5. One-way operations.

6. Harmful effects of unwarranted traffic signals or too-restrictive speed regulation.

7. Increased effectiveness with broad-scale programs.

D. The traffic engineering unit.

1. As a governmental function.

2. As a private enterprise function.

3. The administrative pattern of the unit. (Supervision, responsibility, authority, budget, etc.)

4. The importance of legislative authority. (Policy should assign responsibility to the unit for the technical decisions concerning traffic operation.)

5. Specialized training needed for individuals within the unit. (Formal, inservice, short courses, and conferences.)

E. Principle activities of the traffic engineering unit.

1. Traffic studies. (Problem analysis and determination of corrective treatment.)

2. Traffic improvement measures. (Facilitating traffic flow with such improvements as one-way streets, reversible lanes, curb parking and loading control, turn restrictions, etc.)

3. Traffic control devices. (Guide, warn, and control traffic, inform motorists and pedestrians of specific traffic regulations.)

4. Selective physical improvements. (The use of physical aids and controls, including channelization and refuge islands, crosswalk markings, traffic signals, and pedestrian barriers to alleviate causes of traffic accidents and congestion through highway construction.)

5. Official cooperation with the over-all transportation efforts of a community.

6. Research. (a) Provides a better understanding of traffic operations. (b) Offer evidence to suggest the application of more effective engineering techniques.

UNIT SIX

Traffic Legislation and Judicature

A. Traffic Laws and Ordinances.

1. Their importance in the growing highway traffic problem.

2. A key role in establishing standards of motorist and pedestrian conduct.

3. Based upon sound, realistic principles.

B. Administration, enforcement, and interpretations of traffic laws and ordinances.

C. Uniform vehicle code and model traffic ordinance.

1. Need for uniformity.

2. Desired effect of uniformity.

a. Enable motorists and pedestrians to know and obey rules wherever they go.

b. Make for a more orderly and efficient flow of traffic.

c. Reduce the danger of accidents.

d. Improve the standards for driving licensing.

3. The concept of uniform laws.

a. Acceptable variances.

b. Flexibility

c. Proper balance of uniformity and variance.

4. The effective use of uniformity.

a. Operator and chauffeur license laws.

b. Registration and certificates-of-title laws.

c. Financial responsibility laws.

D. The role of the traffic court in the highway transportation system.

1. Accident prevention.

a. Inculcate voluntary observance of traffic laws.

b. Application of corrective measures to individual offenders.

c. Exercise proper deterrents on violators.

2. Adjudicate cases arising under traffic laws and ordinances.

a. Sound administration of justice.

b. Judicial rights of the defendant.

3. Penalization designed to correct the behavior of the violator.

a. Not intended as a source of revenue.

b. Instrumental in correction through education.

c. A reciprocal relationship with driver improvement schools.

E. The future of the specialist in traffic legislation and judicature.

(It is suggested that the teacher evaluate the interest of the class before proceeding into this topic. Should it become apparent that an interest does exist, a brief survey of the present manpower deployment, and a review of the statistical trend should provide adequate evidence of the future potential. Students may wish to explore beyond this level through resource reading.)

Canham, Erwin D. "A Citizen Looks at Traffic Courts." Traffic Safety, Feb., 1960, pp. 12-13.

(1) Advisory letter

(2) Review examination

(3) Interview (which may result in restricting the driving privilege, or giving him "another chance" before the final action).

3. Registration and titling of vehicles.

a. Effective control over improper or unsafe use of the vehicle.

b. Centralized administration of license tags and vehicle titles. (May vary in some states. Teacher should acquaint himself with the policy in his locality.)

c. Nature and scope of the vehicle registration and titling records system.

4. Motor vehicle administration's role in periodic vehicle inspection.

a. Periodic vehicle inspection as an essential part of the highway safety program.

b. Develop and implement standards of effective vehicle inspection.

c. Supervision of inspection stations.

d. Collection and treatment of data relating to motor vehicle condition. (May be utilized in research, education, citizen support, public information, etc.)

5. Administration of the financial responsibility law.

a. Fundamental purpose of the law. (Drivers show proof of financial responsibility in cases of involvement in motor vehicle accident, or conviction of a major traffic offense.)

b. The law serves many secondary purposes.

(1) Required reports provide valuable information for; driver-licensing activities; enforcement; engineering; education; and other accident prevention measures.

(2) Keep irresponsible drivers off the roads.

(3) Collected data facilitates the review of existing laws and ordinances.

B. Traffic Accident Records Systems.

1. In many states this system is administered by the Department of Motor Vehicle Administration, in others, by the Department of Public Safety. (Cities and counties normally also have accident-records division.)

2. The relationship between good accident records and effective accident-reduction programs.

3. The accident records system is a service agency providing needed accident records and data to all.

4. Sources of information.

a. Drivers

b. Police-investigators.

c. Garages

d. Witnesses

e. Newspaper articles

f. Coroners

g. others

5. Compilation of information.

6. Putting accident data to use.

a. Law enforcement

b. Education

c. Public support and public information.

d. Legislation

e. Driver licensing

f. Traffic engineering

g. Financial responsibility

h. Research

7. The "inert" nature of collected data.

a. Specific analysis required to determine significance of data.

8. Making data meaningful.

a. The establishment of definite patterns.

b. Suggested hypotheses based on statistical treatment of data.

c. Summaries provide necessary data for preparing periodic public reports.

9. The role of the computer in data processing.

a. Increased effectiveness.

b. Speed of compilations.

c. Human analysis of machine computed data.

d. The effect on manpower requirements.

e. Better trained personnel needed to operate the computerized records system.

10. An example* of the variety of manpower functions identified within this unit which require specialized training.

a. Driver license examiner.

b. Driver improvement analyst.

c. Traffic accident records analyst.

d. Data processing and computer specialist.

e. Investigator's (license investigation, financial responsibility investigation, title investigation, etc.)

f. Supervision in the motor vehicle inspection program.

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

PLAN FOR A FACULTY ORIENTATION MEETING

The agenda on this page was planned by a junior high school principal, in cooperation with his curriculum study committee chairman, to introduce a curriculum development project in reading to the entire faculty. The newly formed Reading Improvement Committee had met for the first time the week before. This agenda was distributed to the faculty two days prior to October 14. The hand-written notes at the right are those on the principal's own copy.

AGENDA FOR OCTOBER 14
FACULTY MEETING
Western Junior High School
Cafeteria, 3:00 P.M.

Remind secretary to have coffee and cookies!

Purposes:

To inform faculty of Reading Improvement Committee's tentative plans.
To introduce new reading consultant to the faculty.
To acquaint study committee with specific reading problems facing teachers of subject areas.

Staff needs to know the consultant's special capabilities.

3:00 Introduction by principal of new consultant and reading committee chairman

Give chairman credit for willingness to do a difficult job.

3:10 Report by committee chairman
How the committee sees the problem
Possible ways to proceed with the study
The need to obtain faculty thinking

3:20 Commentary by consultant on problem
General observations
Other schools' experiences with problem

Emphasize need for involvement of all. Everyone in our school has mentioned "the reading problem" at the lunch table!

3:30 Departmental group meetings
Discussions of reading problems faced by teachers
Compilation of written lists of problems in reading for specific areas

3:45 Oral reports to faculty by department chairmen
Highlights of departmental group meetings
Brief comment by consultant

Remind committee secretary to take notes.

4:00 Questions or comments from the floor

4:10 Meeting summary by principal
Clarification of recommendations made in this meeting
Explanation of reading committee's next steps
Set time for committee to report back to faculty

Promise to support committee.

End on time!

4:15 Adjournment

2150

UNIT FIVE

Education and Public Information

A. Education

1. The goals of traffic safety education.

   a. Building responsible traffic citizens.

   b. Conservation of human life.

2. A comprehensive traffic safety education program.

   a. Elementary education's role in the comprehensive program.

      (1) Responsibility for practical traffic safety instructions.

      (2) Assist the child in developing a working knowledge of the rules of the road. (He must relate to the traffic situation as a pedestrian, bicycle rider, and vehicle passenger.)

      (3) Provide instruction which will help the child identify and understand the basic traffic signs, signals and marking.

      (4) Identify physical and mental deficiencies which may underlie behavior leading to accidents. (Faulty hearing, limited vision, emotional s'ress, etc.)

   b. The role of secondary education in the program.

      (1) Driver and traffic safety education.*

         (a) Need for: (Reinforce with current statistical data relating to youthful drivers.)

         (b) Motorcycle safety program.

         (c) Pedestrain safety.

(d) School bus safety.

(e) Purpose of: (1) Promotion of the safe, efficient, and rewarding use of the motor vehicle. (2) Develop high standards of performance and conduct. (3) Foster a sense of responsibility. (4) Nuture patterns of cooperation.

*Driver and traffic safety education constitutes a major function of the secondary safety program. The design of this course limits the dissemination of information relating to this topic; therefore, it has been superficially treated in this outline. The instructor may expand this topic if time permits, or suggest related reading for those students expressing increased interest.

(2) Traffic safety in other basic courses.

(a) Social studies. (Need for improving traffic conditions, analysis of traffic problems, etc.)

(b) Science. (Effects of gravity, friction, and inertia on moving vehicles.)

(c) Health and physical education. (Establish relationship between driving and general health, fatigue, coordination, effects of alcohol and drugs.)

(d) Shop. (Study of automobile design and mechanics.)

c. Adult traffic safety education programs.

(1) Driver education provided by commercial driving schools.

(2) Driver education provided by public school systems.

(3) Driver improvement programs.

(4) Driver training for the career oriented driver. (Commercial vehicle drivers: Truck, bus, etc.)

(5) Driver rehabilitation programs. (Court directed, and for those recovering from physical or mental illness.)

(6) In-service driver education programs for employees of agencies, governmental units and others. (Example: Traffic safety clinics conducted by businesses utilizing a considerable number of motor vehicles and drivers.)

d. Manpower requirements of the comprehensive traffic education program.

(1) Immediate need.

(2) Anticipated need.

(3) Levels of employment opportunities.

(4) Training required.

B. Public Information

1. Public information as a function in the highway transportation system.

a. The public information programs as a useful tool in the general education of the public.

(1) The success of all highway transportation programs rely largely upon public support.

(2) The relationship between public support and public understanding.

(3) The basic functions of the public information programs.

(a) Tell the public the facts about traffic accidents.

(b) Provide individual drivers and pedestrians with the information they need to protect themselves and others against accidents.

(c) Introduce to the public the various services offered by divisions of the highway transportation systems.

(d) Presenting special-emphasis programs when circumstances call for accenting specific problems.

b. Responsibility for the public information service in highway transportation.

(1) Public officials with responsibilities in the field of highway transportation.

(2) Public information media: (Newspapers; magazines; radio and television stations; motion pictures; outdoor advertising; etc.)

(3) Organizations and agencies enrolled in the cause of safety.

c. The role of the specialist in the public information program.

(1) The tasks of the specialist include:

(a) Assembling, tabulating or analyzing information.

(b) Providing facilities to expediate the flow of information to the proper media.

(c) Making information available to media reporters.

(d) Creation and distribution of printed materials.

(e) Preparation of speeches.

2. Education and public information as a prerequisite to organized citizen support of the highway traffic safety program.

a. Public awareness and public action.

b. Citizen traffic safety organizations.

(1) Rural organizations. (To reach the farm population.)

(2) Women's and parent's organizations.

(3) Employers.

(4) Labor unions.

(5) Motor clubs.

(6) Churches.

(7) Social, fraternal, and service clubs.

(8) Civic associations.

c. Functions of the citizen traffic safety organizations.

PLAN FOR A STUDY COMMITTEE MEETING

The agenda on this page was planned by the chairman of the reading improvement committee for a session one week after the meeting outlined on the previous page. It was distributed to the committee two days before October 21. The handwritten notes at right are on the chairman's own copy.

AGENDA FOR OCTOBER 21
READING IMPROVEMENT
COMMITTEE MEETING
Western Junior High School
Lounge, 2:00 P. M.

Double check on the arrangements for released time for teachers to attend meeting!

Purposes:

To review and study lists of reading problems submitted by staff in subject areas
To explore other evidences of reading problems; e.g., reading test scores
To discuss references investigated by consultant

Emphasize importance of follow-through after once involving the faculty.

2:00 Faculty recommendations (Committee secretary)
Distribution of duplicated copies of faculty recommendations of October 14; time to read them
Discussion of report by committee
Tentative conclusions drawn

Remind committee on need to be tentative until all facts are in.

2:20 "Reading Test Scores" (Guidance director)
Explanation of school's testing program
Comparison of test findings with general staff recommendations

Every committee member - and the consultant - must understand the testing program and findings.

2:55 Announcement of conference (Chairman)
Reading instruction program at College in November

Emphasize our solid administrative support - we can call pick representatives.

3:00 Coffee break

3:10 "Pertinent Reading References" (Consultant)
Distribution of written bibliography of applicable materials for committee's study
Discussion of areas of interest for follow-up study by individuals; assignment of materials

3:40 Wrap-up (Chairman)
Summary of day's accomplishments
Review of individual committee responsibilities for next meeting
Consultant to contact a school familiar to him having a similar problem, and bring to next meeting a report of that school's findings
Time of next meeting

Be sure to ask for comments from the floor.

Remind them the next meeting will be after school - can't get enough substitutes.

4:00 Adjournment

UNIT SEVEN

Health, Medical Care and Transportation of the Injured.

A. Health aspects of driver licensing.

1. Physiological conditions which may result in loss of ability to control a vehicle safely.

2. Procedures controlling the denial or revocation of a driving license based on pathological reasons.

3. Special requirements of fitness for commercial vehicle drivers.

B. The nature, magnitude, and contribution of ALCOHOL to the highway accident problem.

1. The effect of blood alcohol concentration on driver behavior.

2. Contribution to highway accidents.

3. Enforcement of the drinking-driver laws.

4. The role of the medical examiner in accident investigation and reporting.

5. The importance of the public understanding the problem.

6. The function of psychiatrically oriented medical clinic in enforcement and judicial processing of the drinking driver.

7. Employment of community resources in the control of the drinking driver and drinking pedestrian.

8. Utilization of citizen support groups.

C. The relationship of DRUGS to highway safety.

1. Beneficial and harmful effects.

a. Many pharmaceutical drugs contribute substantially to highway safety by maintaining the health of their users.

b. The effects of some physician prescribed drugs can decrease the ability of the driver or pedestrian to negotiate safely.

c. The psycho-physiological effects of drugs include modification of judgement, vision, alertness and neuromuscular control.

2. The need for research to elucidate the relationship between drugs and highway safety.

3. The uniform vehicle code states that license to drive shall not be issued to any person who is a habitual user of narcotic drugs.

4. Need for public information and education relative to the problem.

D. Emergency care and transportation of the injured.

1. Magnitude of the problem. (Approximately 46 million persons are injured each year.)

2. Two major classes of emergencies.

a. Conditions which require immediate medical attention.

b. Conditions in which care may be delayed.

3. Emergency care of the patient.

a. First aid at the scene of the accident.

b. Level of care administered the patient at the scene of the accident.

4. Transporting the patient in comfort and safety.

a. Competencies desired of ambulance personnel.

(1) Training in emergency medical technique.

(2) Ability to use ambulance equipment properly.

(3) Experience in determining the relative severity of the patient's condition.

(4) Skill in handling and transporting the patient to the hospital in such a manner as not to aggravate his condition.

(5) Training in the proper way to remove persons from wrecked vehicles.

b. Emergency vehicles should be manned by adequately trained and appropriately licensed driver and an adequately trained attendent.

c. The problem of the "speeding ambulance".

d. Ambulance design. (Emphasize that the vehicle must be equiped with facilities for the handling and care of the patient at the scene and in transit.)

e. Communications: A vital segment in the care and transportation of the injured. (Dispatching - inroute communications - on-the-scene communications - coordinating activities-summoning additional aid - correlating arrival time at hospital.)

5. Increased scope and effectiveness of emergency care and transportation requires:

a. A vigorous program of careful selection and training ambulance drivers and attendants.

b. Provision for continuing refresher training in new techniques, equipment, and procedures.

c. High standards of competency in operating an emergency vehicle.

d. Fully equiped ambulances, designed to provide facilities for maximum care of the injured or ill.

e. Periodic inspection of the vehicle to assure mechanical reliability and dependable emergency equipment.

f. Improved coordination and communication among groups providing emergency care.

g. Adequate recognition and compensation of manpower.

IV

APPRAISING ACHIEVEMENT AND GRADING

An evaluation of the student in a course of this nature would vary with the grading policies of a particular institution, and the student achievement desired by the teacher. However, the author suggests the behavioral modification of the student be measured at the awareness level. This would be in keeping with the generalized course objectives listed under II of this syllabus.

DEVELOPING AND SUSTAINING INTEREST

How does the leader prevent the first fires of enthusiasm from dying out? Some of the principles and practices sketched below should serve. Notice that much attention must be paid to psychological needs such as respect, variety, recognition, and security; these are just as important as professional materials or services.

Show awareness and appreciation of the effort each person makes.

Mention instances casually at meetings. Send members occasional clippings related to their work. Send thank-you notes for jobs well done. Mention a member's contribution to his friends; it gets back.

Help each member to feel a stronger identification with the group.

Promote joint visits to other schools and to conferences. Encourage taping, logs, pictures, and other dramatic testimonials to the group's progress. Be sure each member gets a chance to contribute to the group's work.

Help the group to feel that they are growing in responsibility.

Encourage their participation in interpretation to the superintendent and school board. Urge them to write-up their activities for publication in local papers or educational journals. Enlist them in orienting other teachers to the committee's work.

THE GOOD GROUP MEMBER

Thus far we have emphasized to the leader: "Accept the group. Involve the group. Trust the group."

But it works two ways. Each member of the group has a responsibility, too, if the group process is to work. The group must deserve to be trusted. Here are some important points for each group member to think about:

Do your own thinking.

You don't have to agree with the status leader's proposals. Neither do you have to go along with the proposal most popular with the group. Don't be silent out of courtesy to the person who has persuasively presented his pet idea. Submit neither to leader tyranny nor group tyranny.

Learn to listen to others.

Train yourself to talk less and listen more. Don't just wait impatiently for your turn to talk. A committee is not a debating society--it is a place to get work done, to arrive at consensus on issues.

Maintain a tolerant attitude.

Learn to live with the idea of change. Be willing to accept responsibility. Accept the notion that there are probably more than two sides to every question, and many ways of accomplishing a desired goal.

Trust the leader.

Try to understand and identify with the goals of the group. Recognize the group leader's faults, but give him credit for his good points.

APPENDEX I

The Teacher:

Selection of a competent person to teach a highway transportation survey course may present a problem to many colleges. A suggested approach to this problem is offered below:

The most competent and experienced teacher available would be employed to; (1) present unit one, "Introductory Synopsis," (2) coordinate the entire course of instruction; (3) summarize the course content and evaluate the students. Unit two through seven would be taught by selected resource persons possessing extensive knowledge and a working concept of a specific functional area within the highway transportation system. (For example: Unit four, "Traffic Engineering" may best be taught by an experienced traffic engineer that has demonstrated ability to present information to an assemblage, and conduct meaningful group discussions.)

This course was designed to permit each unit to be taught by an individual resource person. However, an instructor fully competent in more than one of the functional areas of highway transportation, may be effectively utilized in as many units as considered feasible.

APPENDEX II

Course Time Distribution

Suggested time allotment* for each of the seven units of this outline.

Unit	Title	Estimated Time Required
Unit One:	Introductory Synopsis	12 hours
Unit Two:	Police Traffic Supervision.	6 hours
Unit Three:	Motor Vehicle Administration and Traffic Records Systems . . .	6 hours
Unit Four:	Traffic Engineering	6 hours
Unit Five:	Education and Public Information	6 hours
Unit Six:	Traffic Legislation and Judicature	3 hours
Unit Seven:	Health, Medical Care and Transportation of the Injured . .	6 hours
Summary and Evaluation		3 hours
	Total	48 hours

*It should be noted the above time allotment represents only the thinking of this author, and it is not expected to be the most desirabe in all cases. Realistically, the time distribution may best be determined by an advisory committee, after reviewing pertinent data provided by a community survey. (Caution: Care should be taken, when time allotment changes are made, not to unbalance the course content to a degree which would render it ineffective as a survey presentation.)

GROWING THROUGH ACTION RESEARCH

What is action research? It's not much more than the old problem-solving method in fancier clothes. Essentially it says to the teacher, "Look, most research is done in a situation that doesn't resemble yours. What you want is to solve your own problems as skillfully and independently as you can. Action research is one method which can apply to the individual classroom."

These Are The Steps

The procedures for action research are simply these:

Suggest a hypothetical solution--an educated guess at a relationship that may or may not exist if you study the problem carefully.

Plan to test your hypothesis--a procedure that needn't involve complex statistics;this isn't a graduate thesis.

Try out your plan and evaluate it.

Conclude what your data indicate.

Apply what you have learned.

Now do you have world-shaking findings? Of course not. But you have sharpened your method of inquiry so that you are more sure of what will work for you, with your students, under the conditions of the study.

How Does Action Research Apply Here?

Either a committee can follow an action research approach in some of its work, or it can help other teachers to use it.

If it is true that morale grows as people grow, there is little that could help more than the feeling that teachers are gaining in ability to tackle their own problems. What's more, teachers who are doing modest research tend to be most interested in that of others.

A typical action research study is one of immediate, local concern to the teacher. Its results can be put into effect immediately.

Special Help Needed

Action research devours time. But it is better to take time to find out what the problem really is than to move rapidly on a vague problem and end up with nothing.

A good consultant can be of much help in bringing the problem into focus. Not that he is so much smarter. Probably he is not. But he should have training in research procedure. He may also bring a perspective that those who are too close to the situation may not have.

Another special problem is resources. In action research the emphasis is upon change in teaching-learning. To know about change we have to develop evaluation tools, and we may need special materials. Study committees urging an action research approach should insure that reasonable requests for resources can be met.

An Emphasis on Commitment

A perennial committee bugaboo is talk. And talk cannot be clearly focused and diminished until the problem is clear and the directions for action become discernible. That's where the action research stress on problem-definition comes in.

A second problem is getting real personal involvement. It is an old committee tradition to avoid personal exposure to change by immersing ourselves in developing recommendations for change in others. Action research doesn't let us pass the buck.

INTRODUCTION

A MODEL ORDINANCE OR STATUTE REGULATING AMBULANCE SERVICE

Development of this model ordinance or statute began in 1956 when representatives of the medical profession concluded that the medical profession had taken too little interest in preventing trauma, while those responsible for traffic safety were too little concerned with the human salvage operations of the doctors. This resulted in a Joint Action Program sponsored by three organizations, the American College of Surgeons, the American Association for the Surgery of Trauma, and the National Safety Council.

Late in 1959 the policy committee of this group asked the Traffic Conference to develop a model ordinance or statute relating to the transportation of the injured. A special Conference committee was activated representing the several interests involved, including a legal consultant to undertake the task.

The attached is a copy of the ordinance or statute developed after a number of meetings of the committee, and extensive correspondence with many interested groups. Numerous city ordinances and the National Institute of Municipal Law Officers' model were used as a guide. At the October 28, 1962, meeting of the special committee of the Conference, representatives of ambulance associations throughout the country in attendance offered several excellent suggestions which were incorporated. The model was approved by the Traffic Conference on October 27, 1963. Section 8(a) and 10(b)(iv) were amended February 1970, to require ambulance equipment for handling several kinds of emergencies, other than dressing wounds and hemorrhages and additional training for ambulance attendants.

At this meeting it was concluded that such a regulation would be more effective if it became a state law. Therefore, the draft is designed so that with appropriate changes, it may be used also as a Model Statute. Where feasible, it was concluded, a state statute is preferable to a local ordinance.

On page 2, Section 2 Licensing Requirements, it is presumed that where the model is used as an ordinance the city or county has legal authority under state law to adopt special license requirements for ambulances. The legal assumption, which should be verified in each case, is that the city or county has authority under its police power to prescribe regulations necessary to supplement state laws where the public safety and welfare so require. Therefore, it should be expressly understood that, in any state, the model, when adopted as an ordinance, must be modified to eliminate any conflict with existing state laws.

The intent of the model is to serve as a guide to improve a necessary public service and provide uniformity throughout the United States.

A MODEL ORDINANCE* REGULATING AMBULANCE SERVICE

*This model is designed so that, with appropriate changes, it may be used also as a Model Statute. Where feasible, a State statute is preferable to a local ordinance. It has been adapted as a Model State Statute by the Council of State Governments.

A MODEL ORDINANCE REGULATING AMBULANCE SERVICE

An Ordinance to Regulate the Licensing, Inspection and Operation of Ambulances, to Provide Standards for the Licensing of Ambulances and of Ambulance Drivers, Attendants, and Attendant-Drivers, to Provide for Renewal and Revocation of Licenses, to Require Written Reports, to Provide for Traffic Regulations of Ambulances, and to Establish Penalties for Violation of its Provisions.

The (_____) of (_____)
enacting body city or county

ordains as follows:

SECTION I Definitions. Unless otherwise specified, the term "Ambulance" means

(a) any privately- or publicly-owned motor vehicle that is specially designed or constructed, and equipped, and is intended to be used for and is maintained or operated for the transportation of patients, including dual purpose police patrol cars and funeral coaches or hearses which otherwise comply with the provisions of this Ordinance, except any such motor vehicle owned by, or operated under the direct control of, the United States.

(b) "Attendant" means a trained and/or qualified individual responsible for the operation of an ambulance and the care of the patients whether or not the attendant also serves as driver.

(c) "Attendant-Driver" means a person who is qualified as an attendant and a driver.

(d) "Driver" means an individual who drives an ambulance.

(e) "Dual purpose police patrol car" means a vehicle, operated by a police department, which is equipped as an ambulance, even though it is also used for patrol or other police purposes.

SECTION 6 Duties of License Officer

(a) The License Officer shall, within _____ days after receipt of an application for an ambulance license as provided for herein, cause such investigation as he deems necessary to be made of the applicant and of his proposed operations.

(b) The License Officer shall issue a license hereunder for a specified ambulance, to be valid for a period of _____ years unless earlier suspended, revoked or terminated, when he finds:

(i) That the public convenience and necessity require the proposed ambulance service.

(ii) That each such ambulance, its required equipment and the premises designated in the application, have been certified by the Health Officer as provided for herein.

(iii) That the applicant is a responsible and proper person to conduct or work in the proposed business.

(iv) That only duly licensed drivers, attendants and attendant-drivers are employed in such capacities.

(v) That all the requirements of this Ordinance and all other applicable laws and ordinances have been met.

SECTION 7 Duties of Health Officer

(a) Prior to the issuance of any ambulance license hereunder, the Health Officer shall cause to be inspected the vehicles, equipment and premises designated in each application hereunder, and shall certify his approval in a written report to the License Officer when he finds compliance with the standards prescribed in Section 4(a) and in Section 8 of this Ordinance, and with the regulations promulgated under such sections;

(ii) is able to speak, read and write the English language;

(iii) has been found by a duly licensed physician, upon examination attested to on a form provided by the Health Officer, to be of sound physique, possessing eyesight in both eyes and corrected to at least 20/40 in the better eye, and free of physical defects or diseases which might impair the ability to drive or attend an ambulance; and

(iv) for each applicant for attendant or attendant-drivers license, that such applicant has a currently valid certificate evidencing successful completion of a course of training equivalent to the advanced course in first aid given by the American Red Cross or the United States Bureau of Mines and, in addition, has completed successfully a course of training developed by the Department of Transportation or the Department of Health, Education and Welfare, or their appropriate constituent units.

PROVIDED HOWEVER, that no one shall be licensed as a driver or attendant-driver unless he holds a currently valid chauffeur's permit from the State of (_____).

(c) A license as driver, attendant or attendant-driver issued hereunder shall not be assignable or transferable.

(d) No official entry made upon a license may be defaced, removed, or obliterated.

SECTION 11 Renewal of License

Renewal of any license hereunder, upon expiry for any reason or after revocation, shall require conformance with all the requirements of this Ordinance as upon original licensing.

SECTION 12 Revocation of License

(a) The License Officer may, and is hereby authorized to, suspend or revoke a license issued hereunder for failure of a licensee to comply and to maintain compliance with, or for his violation of, any applicable provisions, standards or requirements of this Ordinance, or of regulations promulgated hereunder, or of any other applicable laws or ordinances or regulations promulgated thereunder, but only after warning and such reasonable time for compliance as may be set by the License Officer. Within _____ days after a suspension, the licensee shall be afforded a hearing, after reasonable notice. The Licence Officer shall, within _____ days after conclusion of such hearing, issue a written decision (which shall include written findings) as to the suspension of said license. Such written decision shall be promptly transmitted to the licensee to whom it refers.

(b) The initial, semi-annual or other ambulance, equipment and premise inspection reports of the Health Officer herein provided for shall be prima facie evidence of compliance or non-compliance with, or violation of, the provisions, standards and requirements provided herein, and of the regulations promulgated hereunder, for the licensing of ambulances.

(c) Upon suspension, revocation or termination of an ambulance license hereunder, such ambulance shall cease operations as such and no person shall permit such ambulance to continue operations as such. Upon

(f) "Health Officer" means the (_____) Health Officer
city or county
or other designated official.

(g) "License Officer"* means the (_____)
city or county
(_____).
designated officer

(h) "Patient" means an individual who is sick, injured, wounded, or otherwise incapacitated or helpless.

(i) "Person" means any individual, firm, partnership, association, corporation, company, group of individuals acting together for a common purpose or organization of any kind, including any governmental agency other than the United States.

SECTION 2 License Required*

(a) No person, either as owner, agent or otherwise, shall furnish, operate, conduct, maintain, advertise, or otherwise be engaged in or profess to be engaged in the business or service of the transportation of patients upon the streets, alleys, or any public way or place of (_____) unless he holds a currently
city or county
valid license for an ambulance, issued pursuant to this Ordinance. An ambulance operated by an agency of the United States shall not be required to be licensed hereunder.

(b) No ambulance shall be operated for ambulance purposes, and no individual shall drive, attend or permit it to be operated for such purposes on the streets, alleys, or any public way or place of (_____) unless it shall be under the immediate
city or county
supervision and direction of a person who is holding a currently valid license as an attendant-driver or attendant.

*Where there is a Health Officer, he should be designated as the License Officer.

(c) Provided however, that no such licenses shall be required for an ambulance or for the driver, attendant or attendant-driver of an ambulance,

(i) which is rendering assistance to licensed ambulances in the case of a major catastrophe or emergency with which the licensed ambulances of (_____) are insufficient or unable to cope; or is
city or county

(ii) operated from a location or headquarters outside of (_____) in order to transport patients who are picked up beyond the limits of
city or county

(_____) to locations within (_____),
city or county city or county

but no such outside ambulance shall be used to pick up patients within (_____) for transportation to locations within
city or county

(_____) unless the driver, attendant and attendant-driver and the person subject to the provisions of Section 2(a) of this Ordinance in respect of such ambulance, hold currently valid licenses issued pursuant to this Ordinance.
city or county

SECTION 3 Application for Ambulance License. Applications for ambulance licenses hereunder shall be made upon such forms as may be prepared or prescribed by the License Officer and shall contain:

(a) The name and address of the applicant and of the owner of the ambulance.

(b) The trade or other fictitious name, if any, under which the applicant does business and proposes to do business.

(c) The training and experience of the applicant in the transportation and care of patients.

(d) A description of each ambulance, including the make, model, year of manufacture, motor and chasis number; current state license number; the length of time the ambulance has been in use; and the color scheme, insignia, name, monogram or other distinguishing characteristics to be used to designate applicant's ambulance.

USING RESOURCES WISELY

Human Resources

While instructional aids are important in creating motivation, of even greater importance is the utilization of human resources. These resources should include people from outside, as well as within the school system. The committee might call on guest speakers, state department personnel, county helping teachers, local citizens, parents, college experts, and many others.

However, it should be clearly understood that these people can but supplement, advise, and encourage the staff in their work. There is no denying that the final outcome in the curriculum development process must be the result of local staff efforts in order to be long-lasting. As has been so aptly expressed, "You can't buy an in-service program. A school staff must do it themselves."

Locating Materials

Most study projects require various kinds of research materials and supplementary literature. Location of such materials can be time-consuming and demanding. As in most studies, the committee will wish to search the related field before beginning any action program.

There are several ways that this task can be accomplished in reasonable time:

Certain committee members can be assigned the task of checking the local library for related materials.

The consultant may be able to supply background materials from his own past experiences.

Other committee members may accept the responsibility of writing to certain publishers or sources for appropriate books, pamphlets, or similar materials.

If the project involves the examination of textbooks, these too can be obtained by contacting and inviting in representatives of various companies.

If it is possible to anticipate needs for materials in advance of the establishment of the project, the administration might assign the collection of materials to certain staff members such as the school librarian, curriculum coordinator, or a department chairman. Such preliminary materials could furnish a basis for the formation of bibliographies which can be expanded as the study proceeds.

Reading and Using Materials

It is one thing to gather a vast collection of reading matter on a topic. It is quite a different task to have such material read, analyzed, and culled for that which is applicable to the study being considered. Here the work can be divided up and shared among the committee members. Faculty members not serving on the committee might also be asked to do some reading in relation to this phase of the study.

Brief reports of the highlights of such reading might be submitted to one person on the committee for final compilation and reporting to the committee as a whole. The committee can then evaluate them in terms of their meaning to the study project. A further application of this process would be to distribute summaries to the entire staff. This could be done through a mimeographed flyer, a curriculum bulletin, or directly in a general faculty meeting.

GCIS

2154

(e) The location and description of the place or places from which it it intended to operate.

(f) Such other information as the License Officer shall deem reasonably necessary to a fair determination of compliance with this Ordinance.

(g) An accompanying license fee of $_____.

SECTION 4 Standards for Ambulance License

(a) Each ambulance shall, at all times when in use as such,

(i) be suitable for the transportation of patients from the standpoint of health, sanitation and safety, and be maintained in suitable premises;

(ii) contain equipment conforming with the standards, requirements and regulations provided for herein, which equipment shall be in proper and good condition for such use;

(iii) currently comply with all applicable laws and local ordinances relating to health, sanitation and safety;

(iv) be equipped with such lights, sirens and special markings to designate it as an ambulance as may be prescribed in reasonable regulations promulgated by the License Officer; and

(v) be equipped with approved safety belts for the driver, and for a passenger in the front seat if such seat is provided.

(b) Any change of ownership of a licensed ambulance shall terminate the license and shall require a new application and a new license and conformance with all the requirements of this Ordinance as upon original licensing.

(c) Application for transfer of any ambulance license to another or substitute vehicle shall require conformance with all the requirements of this Ordinance

as upon original licensing. No ambulance license may be sold, assigned, mortgaged or otherwise transferred without the approval of the License Officer and a finding of conformance with all the requirements of this Ordinance as upon original licensing.

(d) Each licensed ambulance, its equipment and the premises designated in the application and all records relating to its maintenance and operation as such, shall be open to inspection by the Health Officer or his designated representatives during usual hours of operation.

(e) No official entry made upon a license may be defaced, removed or obliterated.

SECTION 5 Standards for Ambulance License -- Liability Insurance

(a) No ambulance license shall be issued under this Ordinance, nor shall such license be valid after issuance, nor shall any ambulance be operated in (_____) unless there is at all times in force and
city or county
effect insurance coverage, issued by an insurance company licensed to do business in the State of (_____), for each and every ambulance owned and/or operated by or for the applicant or licensee, providing for the payment of damages;

(i) for injury to or death of individuals in accidents resulting from any cause for which the owner of said vehicle would be liable on account of liability imposed on him by law, regardless of whether the ambulance was being driven by the owner or his agent, and

(ii) for the loss of or damage to the property of another, including personal property, under like circumstances,

in such sums and under such terms as may be required in regulations promulgated by the License Officer.

(b) Said insurance policies shall be submitted to the License Officer for approval prior to the issuance of each ambulance license. Satisfactory evidence that such insurance is at all times in force and effect shall be furnished to the License Officer, in such form as he may specify, by all licensees required to provide such insurance under the provisions of this Ordinance.

(c) Every insurance policy required hereunder shall contain a provision for a continuing liability thereunder to the full amount thereof, notwithstanding any recovery thereon, that the liability of the insurer shall not be affected by the insolvency or the bankruptcy of the assured, and that until the policy is revoked the insurance company will not be relieved from liability on account of non-payment of premium, failure to renew license at the end of the year, or any act or omission of the named assured. Such policy of insurance shall be further conditioned for the payment of any judgments up to the limits of said policy, recovered against any person other than the owner, his agent or employee, who may operate the same with the consent or acquiescence of the owner.

(d) Every insurance policy required hereunder shall extend for the period to be covered by the license applied for and the insurer shall be obliged to give not less than _____ days written notice to the License Officer and to the assured before any cancellation or termination thereof earlier than its expiration date and the cancellation or other termination of any such policy shall automatically revoke and terminate the licenses issued for the ambulances covered by such policy, unless another insurance policy complying with the provisions of this section shall be provided and be in effect at the time of such cancellation or termination.

Provided, however, that under the terms of this Ordinance the Health Officer shall have no responsibility, and shall exercise no authority, in connection with laws and ordinances of general applicability which deal with motor vehicle inspection.

(b) Subsequent to issuance of an ambulance license hereunder, the Health Officer shall cause to be inspected each such licensed vehicle, and its equipment and premises, whenever he deems such inspection to be necessary but in any event no less frequently than twice each year, and shall promptly report his findings in a written report to the License Officer. The periodic inspection required hereunder shall be in addition to any other safety or motor vehicle inspection required to be made for ambulances or other motor vehicles, or other inspections required to be made, under general law or ordinances, and shall not excuse compliance with any requirement of law or ordinance to display any official certificate of motor vehicle inspection and approval nor excuse compliance with the requirements of any other applicable general law or ordinance.

(c) A copy of each initial, semi-annual or other ambulance, equipment and premises inspection report submitted by the Health Officer to the License Officer under the provisions of this section shall be promptly transmitted to the applicant or licensee to whom it refers.

SECTION 8 Standards for Ambulance Equipment

(a) Required equipment in each ambulance shall include, at all times when the ambulance is in use as such, equipment adequate in the judgment of the Health Officer for light rescue, protected extrication, dressing wounds,

splinting fractures, controlling hemorrhage, providing oxygen, assisting respiration, monitoring blood pressure, pulse and respiration rates, assisting in emergency childbirth and management of mentally deranged.

(b) The Health Officer is authorized and directed to promulgate regulations, after public notice and opportunity for public hearing, to implement the standards provided herein as to required equipment in ambulances. In determining the adequacy of equipment, the Health Officer shall take into consideration the current list of essential equipment for ambulances, adopted by the American College of Surgeons or its duly authorized Committee on Trauma. Each licensee of an ambulance shall comply with such reasonable regulations hereunder as may be promulgated by the Health Officer and shall maintain in each such ambulance, at all times when it is in use as such, all such equipment as may be prescribed by the Health Officer hereunder.

SECTION 9 Applications for Drivers, Attendants and Attendant-Drivers License

Applications for drivers, attendants and attendant-drivers licenses hereunder shall be made upon such forms as may be prepared or prescribed by the License Officer and shall contain:

(a) The applicant's full name, current residence, places of residence for _____ years previous to moving to his present address, and length of time he has resided in (_____).
city or county

(b) The applicant's age, marital status, height, color of eyes and hair.

(c) Whether he has ever been convicted of a felony or misdemeanor, and if so, when and where and for what cause.

(d) The applicant's training and experience in the transportation and care of patients, and whether he has previously been licensed as a driver, chauffeur, attendant or attendant-driver, and if so, when and where, and whether his license has ever been revoked or suspended in any jurisdiction and for what cause.

(e) Affidavits of good character from two reputable citizens of the United States and residents of (_____) who have
city or county
personally known such applicant and observed his conduct during _____ years next preceding the date of his application.

(f) Two recent photographs of the applicant, of a size designated by the License Officer, one of which shall be attached by the License Officer to the license.

(g) Such other information as the License Officer shall deem reasonably necessary to a fair determination of compliance with this Ordinance.

(h) An accompanying license fee of $_____.

SECTION 10 Standards for Drivers, Attendants and Attendant-Drivers License

(a) The License Officer shall, within a reasonable time after receipt of an application as provided for herein, cause such investigation as he deems necessary to be made of the applicant for a drivers, attendants or attendant-drivers license.

(b) The License Officer shall issue a license to a driver, attendant or attendant-driver hereunder, valid for a period of _____ years, unless earlier suspended, revoked or terminated, when he finds that the applicant

(i) is not addicted to the use of intoxicating liquors or narcotics, and is morally fit for the position;

ACKNOWLEDGMENTS

The Automotive Safety Foundation and the Highway Users Federation for Safety and Mobility was fortunate to have DR. JAMES E. CARNAHAN of Michigan State University serve as the principal investigator and writer for the highway safety program managment syllabus. During the project work, Dr. Carnahan gave freely of his personal time while continuing to carry out his duties as Coordinator of Research and Development at the Highway Traffic Safety Center, Michigan State University.

Dr. Carnahan brought to this work a valuable technical competence and a talent for deliberate investigation. We are indebted to him for his productive organizational ability and overall contributions to the project.

In addition to Dr. Carnahan, the contributions of many people have made this syllabus possible. The Automotive Safety Foundation and the Highway Users Federation wish to express their appreciation to the following persons who actively participated in the syllabus development and review.

suspension, revocation or termination of a drivers, attendants or attendant-drivers license hereunder, such driver, attendant or attendant-driver shall cease to drive or attend an ambulance and no person shall employ or permit such individual to drive or attend an ambulance.

SECTION 13 Reports

(a) Within _____ hours after transporting any patient within (_____ city or county), or from one place within (_____ city or county) to another place within or beyond its limits, the licensee of an ambulance hereunder shall file a written report with such (_____ designated official) of (_____ city or county) upon such form as they may provide or prescribe, giving all information therein required and any other relevant information which such (_____ designated official) may require.

(b) The provisions of subsection (a) of this section shall apply with equal force in case such patient shall die before being so transported in such ambulance or dies while being transported therein or at any time prior to the acceptance of the patient into the responsibility of the hospital or medical or other authority if the patient is still under the care or responsibility of the ambulance.

SECTION 14 Obedience to Traffic Laws, Ordinances and Regulations

(a) The driver of an ambulance, when responding to an emergency call or while transporting a patient, may exercise the privileges set forth in this section, but subject to the conditions herein stated, and only when such driver has reasonable grounds to believe that an emergency in fact exists requiring the exercise of such privileges.

(b) Subject to the provisions of subsection (a) hereof, the driver of an ambulance may

(i) Park or stand,
provisions of

(ii) Proceed past a
after slowing

(iii) Exceed the max
or regulation
erty; and

(iv) Disregard laws
or movement or

(c) The exemptions herein gr
making use of audible ar
law, ordinance or regula

down as may be necessary for safe operation;
imum speed limits permitted by law, ordinance
so long as he does not endanger life or prop-

, ordinances or regulations governing direction
turning in specified directions.
anted shall apply only when such ambulance is
d visual signals meeting the requirements of
tion.
shall not relieve the driver of an ambulance
ith due regard for the safety of all persons,
s protect the driver from the consequences of
for the safety of others.

failing to comply with, the provisions of
dinance and the applicable provisions hereof
g of ambulances, shall be deemed guilty of a
viction thereof shall be fined an amount not
prisoned for a period not exceeding _____ days,
imprisoned, for each offense.
failing to comply with, any other provision of
deemed guilty of a misdemeanor and upon conviction

thereof shall be fined an amount not exceeding $_____ or be imprisoned for a period not exceeding _____ days, or be both so fined and imprisoned, for each offense.

(c) Each day that any violation of, or failure to comply with, this Ordinance is committed or permitted to continue shall constitute a separate and distinct offense under this section and shall be punishable as such hereunder; provided, however, that the Court may, in appropriate cases, stay the cumulation of penalties.

SECTION 16 Separability

If any section, subsection, sentence, clause, phrase or portion of this Ordinance is for any reason held invalid or unconstitutional by any court of competent jurisdiction, such portion shall be deemed a separate, distinct and independent provision and such holding shall not affect the validity of the remaining portions hereof.

SECTION 17 Effective Date. This Ordinance shall become effective on

(_____)
date

SECTION 18 Ordinances Repealed. All ordinances and parts of ordinances in conflict with the provisions of this Ordinance are hereby repealed as follows:

THE IMPORTANCE OF COMMUNICATIONS

All phases of school life involve a great need for good communication. In the curriculum development process, the need is very specific. At all levels, there must be a clear understanding of purposes and procedures at all times. The only way to achieve such an objective is to assure an active program of information for everyone concerned.

There are many techniques by which good communication can be fostered.

Staff Meetings

As progress is begun and continued in a curriculum development project, information can be made available to the entire staff through many types of meetings:

General faculty meetings
Committee meetings
Small faculty group meetings, such as departments
Grade level meetings
In-service workshops or conferences
Informal discussions
Panel discussions

Written Materials

Many types of written communication are available to a committee to explain its work:

Regular issues of curriculum bulletins
Mimeographed releases by chairman or administration
Duplication of minutes of meetings
Formulation of staff handbooks
Personal notes and letters by the chairman to committee members and consultants
Newspaper publicity releases which will be read by faculty, students and parents

Personal Involvement

Let us face the fact that some people daydream in meetings and seldom read written bulletins. Here are some ways to personally involve other staff members, which committee members may wish to try:

Invite a panel of observers, some whose position is positive, some negative, to attend a committee presentation and react to it.

Talk over a particular suggestion for curriculum improvement with one other faculty member for his reaction.

If you are trying out a piece of action research, invite a faculty member not on the committee to help you with it.

Communication with Outsiders

If the school is working with an outside curriculum organization, college, or consultant, then it is very important that a close contact be established and maintained among the people involved. It is not uncommon for misunderstandings to arise as the result of misinterpretation or lack of information. If this is not given careful attention, ill will and loss of rapport can easily be the result.

For the Advisory Committee for Development of a Syllabus
on Highway Safety Program Management

This Project was Funded by the Automotive Safety Foundation
and Administered by the
Highway Users Federation for Safety and Mobility

PREFACE

With the enactment of the Highway Safety Act of 1966, many highway administration functions became elements of a cohesive highway safety program management system. Many federal, state and local highway programs were restructured to take advantage of strengths inherent to a systemized methodology. With the implementation of the system's approach, certain manpower training and retraining problems became apparent. Skilled and knowledgable highway safety program management personnel were needed immediately, and the colleges and universities were called upon to provide the necessary educational programs. As in the past, the colleges and universities answered the quest, and provided programs of instruction designed to accomplish the identified objectives.

However, the educational institutions were faced with a critical shortage of highway safety program management resource materials. In an effort to provide the best possible program, each institution developed courses of instruction utilizing the highway safety resources accessible to them in their area. This effort generally resulted in a wide variance in course content between the schools. Recognizing this instructional inconsistency, highway safety and college administrators explored the related disciplines and concluded that there was a common core of knowledge essential to highway safety program management, but it was not clearly defined.

For many months the Automotive Safety Foundation, functioning through the staff of the Highway Users Federation for Safety and Mobility, explored the possible role it may play in assisting the highway safety and college administrators in dealing with this manpower training problem. In 1969 it adopted a two-part plan of action. The first part of the plan called for the development of a highway safety program management information base in syllabus form. The syllabus would identify a core of knowledge that would be compatible to the system approach of highway safety program management and be applicable to most state and local highway safety program offices. The second part of the plan called for the printing and distribution of the completed highway safety program management syllabus.

With the printing and distribution of this syllabus, the plan conceived in 1969 has been carried out. However, it should be noted that the Foundation does not consider this resource manuscript to be the solution to the training problem, but rather the beginning of an extensive highway safety management manpower preparation effort. Much remains to be done before a wide-spread, comprehensive highway safety management personnel training program can be effected. Training funds must be identified, curriculums designed and approved, additional resources (e.g., textbooks, films, video tapes, case study manuals) developed, credit and non-credit courses structured, in-service training programs established, etc.

The tasks yet to be done are formidable indeed. But through the combined and coordinated efforts of the state, local and federal governments, colleges and universities, and the private sector, fully effective highway safety manpower training programs are becoming a reality.

AUTHOR'S FOREWORD

Australian Road Models of the Highway Design Formulation for Rural and Semi-Urban Roads are developed considering an average condition on earth, 1963, for overall with the development of a highway design management Guideline. The Rural Condition Analysis was held in St. Louis, Kansas, September 11-12, 1963. The process was focused by Mr. Jack Hosey with the involvement of the Core in Detail.

The road network was developed on the 1st. Core Analysis with the various Committee members in attendance (Accordingly Core Analysis Group). In. Jack Hosey Committee of the Highway Traffic Safety Center of Highway Research Program was chosen as Core Leader to develop an outline for the Highway Design as Core Coordinator. Then employed Discipline Leaders who prepared Overall Design Guidelines. The Core Leader prepared a Highway Design Management Guideline and presented it to the Highway Design Committee in December, 1963.

The Core Leader Committee developed a Guideline from the overall Analysis Committee and Design of the Highway Design Management Guideline. The Core Leader Committee developed the Guideline for Rural Roads and Semi-Urban Roads. The Core Leader Committee developed the Guideline for Rural Roads and Semi-Urban Roads. The Core Leader Committee developed the Guideline for Rural Roads and Semi-Urban Roads.

1000. Information	

c. Inadequate reporting and records

d. Fragmented responsibilities

2. Reducing the consequences of collisions

a. Highway design

b. Vehicle design

3. Multi-faceted nature of highway safety management

a. Numerous agencies involved

b. Various participants make public policy decisions

4. Insufficient manpower development

a. Need for informed, interested and competent leaders

b. Need for many types of traffic safety workers

c. Need for research into education and training programs

5. Insufficient public support

a. Apathy of the public

b. Lack of organized support of official programs by the public sector at local, state and national level

c. Poor relations between citizen support organizations and government officials with traffic safety responsibilities

6. Insufficient attention from public officials

a. Apathy of public officials

b. Insufficient preparation and training of government officials having traffic safety responsibilities--local, state, and federal level.

21839

c. Lack of coordinated effort between government agencies, each having a different responsibility in the total highway traffic safety effort

D. Reducing the incidence of traffic crashes

1. Accident losses can be reduced

a. Value judgment regarding public desires

(1) Some risks will be taken

(2) Public not willing to have extreme controls

(3) Development of the public "will" or desire for safety

b. Trade-off syndrome

(1) Paradox of mobility vs. safety

(2) Conflict between individual and system objectives

c. Finding the acceptable balance

(1) Establishing acceptable controls

(2) Applying enforcement tolerance

(3) Maintaining public acceptance

(4) Encouraging individual conformity

2. Factors utilized in reducing accidents

a. Primary factors

(1) Highway engineering programs

(a) Primitive systems

(b) Right of private access

(c) Primary and secondary roads

AUTHOR'S FOREWORD

President Grant Mickle of the Highway Users Federation for Safety and Mobility established an Advisory Committee in July, 1969, to assist with the development of a Highway Safety Management Syllabus. The first Committee meeting was held in St. Louis, Missouri, September 11-12, 1969. The project was managed by Dr. Jack Weaver with the assistance of the late Al Head.

The over all plan was developed at the St. Louis meeting with the various Committee members in attendance contributing their initial inputs. Dr. James Carnahan of the Highway Traffic Safety Center of Michigan State University was asked at this time to draft a skeleton outline for the Syllabus based on Committee deliberations. When completed (October 1969) the project manager caused the outline to be printed and distributed to the Committee membership.

The Committee member responses to the outline were routed to Carnahan who incorporated the ideas and recommendations of the members into the Syllabus format and then proceeded to research pertinent content areas so as to prepare the total document. The first draft of the complete Syllabus was submitted in July 1970.

A Review Committee was then selected by the Highway Users Federation to critique and react to the Syllabus.

CHAPTER V

The Roles to be Played

What roles are necessary in evolving curriculum revision through local efforts in cooperation with an outside consultant and an area study council? You will note on the following pages that some common threads run through the various statements about the roles.

These threads include:

An assumption of competence in one's chosen position, discipline, or subject field.

The belief that each person has an important contribution to the success of the project.

A need for adequate communication among all members of the team.

A need for mutual support among all those concerned with a project.

The idea that good human relationships are essential to this work.

Important references for this chapter include AASA-ASCD (1), ASCD 1961 (4), ASCD 1964 (6), ASCD 1965 (9), Buell (12), Burnham (13), Douglass (17), Miel (20), Prestwood (26), and Wiles (33).

2156

This Review Committee consisted of members from the parent Advisory Committee and Users of the document from both state and local levels of government. This group met in Memphis, Tennessee in August, 1970, to discuss and finalize revisions they had made on the Syllabus. The changes were incorporated into the document and a revised draft was completed in September 1970.

The Revised Draft (Second Draft) of the Syllabus was then routed to specific readers for review and editorial comment. Recommendations and suggestions from the editorial reviewers were incorporated into the document. The author then prepared a final Syllabus Manuscript and submitted it to the Highway Users Federation in December 1970.

PART I

Overview

THE HIGHWAY TRANSPORTATION SYSTEM

I. General Description of the Highway Transportation System

A. Definition of transportation systems

1. Definition of any system

"An orderly arrangement of components and sub-systems that serve to perform some task in a given environment." (#35, p. 19)

2. Definition of highway transportation system

"A sub-system of transportation system composed of many man-machine-environment combinations interacting in a loosely coordinated fashion." (#35, p. 19)

B. Sub-systems of transportation system

1. Water

2. Rail

3. Air

4. Highways

5. Pipeline

6. Military

C. Relationships of components in transportation system.

1. System components

a. Man

b. Machine

c. Environment

3. More travel per capita

4. More travel per vehicle

5. More vehicles

E. Driver education

1. Effective program mandatory to handle problem cited in C-4 above.

2. Changing costs.

III. The Highway Accident Problem

A. Description of problem

1. Accidents are a system failure -- not simply a component failure

2. An accident is an occurrence in a sequence of events which usually results in death, injury or property damage.

3. Multiple-Cause theory.

B. Nature and scope of the problem

1. Increase in number of vehicles led to increase in potential conflicts

2. Traffic conflict characteristics

3. Theories related to accident causation

4. Factors that contribute to accidents

C. Obstacles to reducing accidents

1. Insufficient data base.

a. Poorly trained investigators

b. Insufficent research

2. Components inter-relate

3. Tasks are performed by both man and machine

D. Nature and purpose of highway transportation system

1. Purpose of system

a. To move people and goods

b. In a safe, rapid and efficent manner

2. Components of system

a. Roadways

Millions of miles of roadway varying in design, construction, and condition.

b. Vehicles

Millions of vehicles of various styles, ages, and conditions.

c. Users (operators)

Millions of operators of varying ages, skill, knowledge, and temperment.

3. Role of institutions in the system

a. Government

b. Business

c. Industry

d. Social

e. Educational

4. Criteria for measuring system effectiveness

a. Safety

b. Volume

c. Speed

d. Convenience

e. Cost

f. Environmental control

II. Trends and Development in the Highway Transportation System

A. Roadway system

1. Interstate urban

2. Interstate rural

3. Other urban

4. Other rural

5. Spot improvements

B. Traffic characteristics

1. Relative traffic densities

2. Traffic patterns

3. Traffic volume

C. Driver population

1. Increase in population -- gravitation towards large population centers

2. Increase in number of drivers

3. Increase in vehicle ownership

4. Change in age structure of drivers

D. Travel Mileage

1. Increased vehicle mileage

2. Shift from rural to urban driving

MICROCOPY RESOLUTIO
NATIONAL BUREAU OF ST

THE SUPERINTENDENT'S ROLE

He makes the decision to do something about curriculum development.

He solicits the advice of his staff, but the recommendation to the school board to use an outside consultant or to join a regional study council is his considered responsibility.

He works closely with the building principals of the district.

In relation to a curriculum study, he draws upon the principals' knowledge of staff abilities and needs.

He chooses a local study chairman and supports him.

If the chairman is not now in the school district's power structure, either officially or unofficially, the superintendent gives him special support and advice. He lets the chairman know what is expected of him and what the limits of his authority are. He is sympathetic with the chairman's problems. He works out with the chairman the best way of selecting the committee.

He helps the chairman and study committee members see the need for the project.

He explores with them not merely the district's need, but their own need for the proposed study. He explains the need for outside help, and the reasons he has recommended a consultant and/or regional study council membership.

He gets to know the regional study council representative and the consultants.

He is involved in the final selection of the consultant, and takes time to acquaint the consultant with the district and its problems and expectations.

He involves the total faculty.

This does not mean that every faculty member must be on a committee. It does mean that provision is made, with the help of the consultant, for making the faculty aware of what is going on and inviting cooperation.

He provides continued support for the project.

He provides materials, books, and secretarial help requested by the committee. He provides funds for substitutes so that committee members may have some released time for local meetings, preparation of reports, attendance at conferences, and visitation days to other school systems. He supports the committee against outside pressure groups seeking to dictate to it. He explains the committee's project to the staff, parents and school board. He shows enthusiasm and interest for the committee's work, and gives encouragement and recognition. He follows through.

He understands that real curriculum change is a slow process.

He is trying to change human behavior. He realizes that this does not change because of a speech in a faculty meeting or the publication of a new outline, but that it changes only with commitment, involvement, action, and time. The superintendent is satisfied with reasonable progress each year, and does not expect the millenium.

ON TEST CHART

TANDARDS-1963-A

(d) Limited access approach

- Expressway
- Freeway
- Parkway

(e) Functional classification of highway system for planning, design, and operation of facilities

- Land service vs. traffic services

(f) Reducing severity of crash

- Breakaway signs
- Improved median barriers
- Paved shoulders
- Object free right of ways
- Elimination of curves
- Multi-lanes and auxiliary lanes
- Spot improvements

(2) Traffic engineering

(a) Control of traffic

- Signs, signals, markings
- Traffic surveillance
- Correcting high accident locations

(b) Uniform traffic control devices

(c) Accident analyses

(d) Vehicle storage

(e) Coordination with other modes of transportation

(3) Automotive engineering

(a) Evolution of vehicle safety

(b) Crash-injury research

(c) Vehicle safety standards

(d) Current vehicle design

(4) Motor Vehicle administration

(a) Driver licensing and driver improvement

(b) Registration and titling

(c) Motor vehicle inspection

(d) Financial responsibility

(e) Reciprocity

(5) Enforcement programs

(a) Policing the highways

- Various law enforcement systems

  . State
  . Regional
  . County
  . City

- Control of interstate system

(b) Adjudicating traffic matters

- Civil action

- Criminal action

- Quasi-criminal action

(6) Education programs

(a) Traffic and safety education

- Elementary schools
- Middle schools
- High school driver education
- Adult driver and safety education

(b) Violators schools

(c) Commercial driving schools

(d) Driver improvement schools

(e) Higher education programs

b. Other factors utilized in reducing accidents

(1) Governmental services

(a) Programming to meet standards and reduce crashes

(b) Legislative action at all governmental levels

(c) Executive action at all governmental levels

(2) Post crash services

(a) Emergency medical care

(b) Transportation of injured

(c) Debris clean up and removal

(3) Fleet safety supervision

(a) Commercial fleets

(b) Private fleets

(c) Public fleets

PART II

NATURE AND CHARACTERISTICS OF MANAGEMENT SYSTEM

(Simply The State of The Art of systems without endorsement necessarily of any system)

I. Fundamental Management Goals

A. To manage means to manage with a purpose

B. First step toward enhancing highway safety management thus must be the quest for a common purpose

1. Discover what is socially desirable

2. Do not yield to only that which is technically feasible

3. Implementation of this step raises question about adequacy of our present methods for assessing public philosophy and opinions

C. Advanced analysis requirements

1. Management now has unprecedented means to illiminate possible unwanted consequences

2. Advance analysis capabilities now permit use to improve our technique before applying them

a. Minimizes need for subsequent costly or politically difficult correction measures

3. Depend on new form of planning capability

a. Purpose to examine long term consequences of management activities

b. Concern for quality of the environment

(1) Quality involves achievement of harmony among potentially conflicting uses

B. New approach

1. In order to attain benefits from highway safety technology we need fresh approach flowing from

   a. Concepts of use

   b. Relationships among institutions involved

   c. Legal principles

   d. Ideology

2. To aid this analysis a new model will be needed

   a. Model as used here is rhetorical device referring to the analytical tools necessary for dealing with highway safety management

   b. Over come barrier of compliance with minimal requirements of national standards

   c. Model would follow principles applicable to catholocity of highway safety system

   d. Questions that arise:

      (1) What intelligence should be portrayed in the model?

      (2) What is its ultimate purpose?

   e. Proposed rationale for model and enhancing management of highway safety technology

      (1) Technology is properly thought of as concerned with the means

      (2) Management of technology involves notion of ends as well as means

      (3) Concept of managing technology is a relatively new abstraction

         (a) Has taken hold due to technology being ineffectively managed by human institutions

(4) Control center for accident data

(a) Coordination of various agencies concerned

(b) Information storage and retrieval

II. Management of Highway Safety Technology

A. Historical approach

1. Society has increasingly failed to manage technology successfully

   a. Many problems of today are second or third order consequences of a technology adopted for a particular goal

   b. Although goal may have been met, its accomplishment has resulted in serious and unwanted effects that now require emergency correction

   c. More deliberate and accurate assessment of technological side effects could have headed off some of the costs we now face

2. Management of highway safety technology has been directed toward facilitating safe and speedy transit

   a. Design characteristics

   b. Traffic flow patterns

   c. Volume and speed

3. Did not sufficiently convey issues of

   a. Legal subdivisions

   b. Cultural aspects

   c. Economic development

   d. Wastemanagement (pollution)

   e. International character

      (1) National defense

      (2) International signing

      (3) Reciprocity

(b) Has inflicted damage on our environment

(c) Application of concept is tentative and untried

(4) Definition

(a) "Technology" is the complex process by which a technique is successfully applied to achieve a selected purpose

(b) In contemporary terms, techniques are based more on engineering research than on empirical experience or craftmanship

(5) To translate specialized knowledge into effective accomplishment, techniques must be afforded appropriate institutional vehicle

(a) Must have capacity for decision-making

(b) Must incorporate regard for risk

(c) Must provide means for raising capital

(d) Must mobilize specialized manpower

(e) Must articulate with both the public and other surrounding enterprises that affect it

(f) Must provide platform for leadership

(6) Institution must have capacity to cope with change and to innovate

(a) Ability to collect and analyze information

(b) Undertake "pre-crisis" as well as "post-crisis" studies

(c) Generate new knowledge

- perform necessary research to extend and refine techniques on which organ was initially founded

- may spawn subsidary programs with goals to extend knowledge

(7) Development of harmonous relationship among institutional components drawn from several familiar groupings

(a) National government

(b) State governments

(c) Local governments

(d) Public and private organizations

(e) Academic institutions

(8) Management of all components of highway safety technology

(a) Involves

- stimulation

- control

- administration

- coordination

- regulation

(b) Optimized so that the aggregate activity may best serve a particular purpose

THE IMPORTANCE OF THE SUPERINTENDENT

The entire educational program depends upon the leadership and support provided by the superintendent. It is recognized, therefore, that any curriculum study is but a part of a large picture. In this very fact there exists an obstacle to success.

Because the superintendent does have a great responsibility and must concern himself with a multitude of details, there is danger that he lose sight of the problems that teachers face in working with curriculum projects.

Follow-Through

Sometimes superintendents are instrumental in beginning programs for curriculum improvement, only to seem to lose interest after the project gets underway. Some superintendents see their role as prime movers, and forget there is a need for a follow-through.

If a superintendent wants worthwhile results from a study, he must be willing to offer his continuing support at all stages of the project. Such support may take the form of interpreting the proposed program to the Board of Education in order to obtain financial backing. It may mean helping to establish and clarify objectives or goals, occasionally meeting with the working committee to keep posted on developments, or simply writing a note of thanks to some staff member for a job well done.

Financial Support

Any program of curriculum development worthy of its name will undoubtedly entail additional expense to a school district. Even if the staff were to restrict its work to within the school with no outside help of any kind, there would still be added expense, probably in the form of needed materials or books. But, where a school system desires more than a minimal attempt at curriculum improvement, the administration must make plans long before the actual work gets underway.

Budget Items

A superintendent faced with the task of formulating his annual budget should give consideration to the following items, when planning a curricular improvement program in his school:

Funds for research or working materials based on an estimate of need for the study group and faculty. Examples: books, pamphlets, film rentals, tapes, and subscriptions.

Fees for membership in curriculum associations or councils.

Consultant fees.

Funds for any special equipment involved in anticipated experimentation. This might include, for example, standardized tests, special toys for kindergarten, specific kinds of maps.

Expenses for substitutes so that there may be a released-time policy for meetings and conference attendance.

Expenses for trips and conferences to be attended by the working committee. These would include travel, registration, and luncheon fees.

Cost of in-service institute days.

(c) Requires

- "early warning system" and corresponding discipline if newly generated technology is not to induce undesired side effects inadvertently, through narrow application

- Urgent to recognize this management precept

  . in present era of transition from time when man utilized technology to protect himself from environment

  . to one in which technology is needed to protect the environment from man and his technology

(9) Technology mangement goes beyond resource management

(a) In its concern

- for technique and tools

- for development of new materials

- with conservation of environment

(b) Concept requires systems approach

- takes into account interactions that occur in management process

- activity of various institutional groups involved in technological development

- all potential uses of system must be considered rather than only movement of people and goods

- motor vehicle "crash loss" factor
- waste disposal
- time loss factor
- space allocation factor

- harmony among uses is object of planning
  - sees that no single-purpose use unwittingly pre-empts options for future

II. Structure for Implementation (theory behind NHSB - as author sees it)

A. Steering mechanism with independent analytical facilities to aid in national decision-making

B. Analyses should be based upon, but not dependent upon, facts developed by federation of states and local governments

C. Minimize violence to present structure, limiting it to those changes necessary to achieve stated purpose

D. Thus, some national authority required to help in management of highway safety technology

1. Authority should function as planning and coordinating body

2. Develop cooperative effort from a wide variety of public and private enterprises to meets its objectives

3. Would have option of taking initiative to meet nationally agreed upon goals if randomonly initiated by users leave critical gaps

4. Authority is equipped to collect and disseminate information about highway traffic envirnoment

5. Should undertake long range studies of resource potential

6. Should make management analysis to predict consequences of projected uses

7. Would assess unmet needs and opportunities that cross jurisdictional lines of interstate organizations

8. Would recommend priorities for programs

9. Advocate development of new techniques necessary for optional use of highway transportation system

III. Types of Management Systems and/or Techniques (#13)

A. PERT -- Program Evaluation and Review Technique

1. Developed for nonstandard situations (not good as model)

2. Objectives of PERT cost

a. Aid development of realistic project estimate

b. Compare estimated and actual cost

c. Determine best allocation of resources to project activities

d. Forecast total project cost

3. Use of cost estimate

a. Start when work structure is formulated

b. Base upon program elements and work units

c. May be computed for individual activities

4. Application of cost estimate

a. Basic

b. Resource allocation

c. Time cost

5. Implementing PERT technique

a. Point of implementation

(1) Proposal development

(2) Program planning

b. Network processing

(1) Manual

(2) EDP - Electronic Data Processing

c. Reports

(1) Project outlook report

(2) Milestone report

(3) Analysis report

d. Project updating

(1) Normal interval updating

(2) Unique updating at intervals

e. Providing management support

(1) Published policy

(2) Personnel training

6. Operational considerations

a. Contractor requirements

b. Internal management requirements

c. Project nature

d. Project duration

e. Project complexity

B. PPBS -- Planning-Programming-Budget System (#47)

1. Philosophical base of structure is formed by single concept dealing with accountability

2. Eight mainstructure members

   a. Objectives

   b. Programs

   c. Program alternatives

   d. Outputs

   e. Progress measurements

   f. Inputs

   g. Alternative ways to do a given job

   h. Systems analysis

3. Basic concept: Accountability

   a. PPBS is multi-purpose system

   b. When implemented properly has a variety of uses

   c. Concept is that each agency is accountable to chief executive

      (1) Focuses attention of each agency on question of what is our role

      (2) Provides a basis for particularizing answers to the questions:

         (a) Accountable for what product?

         (b) Delivered to whom?

d. Explicit business of each agency is to satisfy the public's actual and potential market demands for the agency's particular product/service lines

e. Accountability discharge becomes subject to evaluation in terms of each agency's success in:

(1) gauging the nature and proportions of market demands

(2) fulfilling these demands

4. Apex-term of PPBS structure is "objectives"

a. Each agency is supposed to generate explicit market objectives

(1) To make possible an agency wide understanding

(2) To permit a common agency approach toward their achievement

b. Customer-oriented market objectives are destined to become key standards for agency self-appraisal and accountability

5. Idea of the term "program"

a. A package which encompasses each and every one of the agency's efforts to achieve a particular objective or set of allied objectives

b. Individual activities, functions, and professional disciplines are the antithesis of programs in PPBS sense

c. Idea is to facilitate:

(1) The drawing together

(2) The summation of all agency efforts to meet particular objectives

(3) So as to validate each program and assess in terms of:

(a) overall approach

(b) dimension

(c) costs

(4) Compare with other programs

d. There is strong conceptual relationship between objectives and program

(1) In PPBS language there are no objectives recognized except those which suggest a program designed specifically to fulfill them

(2) There can be no recognized program unless it is designed to accomplish explicit objectives

6. Program alternatives

a. Other possible programs besides those already decided upon

b. Suggests a comparison of two or more possible program approaches

7. Output

a. Idea is inseparably linked to idea of objectives and programs

b. Service produced must satisfy

(1) An explicit market objective

(2) Must be an indicator of program results

8. Progress measurement

a. Program fulfillment must imply that two conditions have occurred

(1) The output which has been planned has materialized

(2) The output distribution which had been intended has been completed

b. Progress then must imply one of two questions:

(1) Either, how closely does the production progress match planned progress?

(2) Or, how well is the output distribution proceeding as compared with the distribution plan?

9. Input

a. PPBS definition close to the traditional use of term

b. The total quantity of manpower, facilities, equipment, and materials applied to program, expressed in either units or dollars, is the program input

10. Alternative ways to do a given job

a. Input related concept

b. The "given job" notion means output has already been decided upon

c. Question is can we alter production and by doing so improve either:

(1) The timing of the production, or

(2) The quantity or quality of the item, or

(3) The unit or total cost of the production

11. Systems analysis

a. Is not the same as PPBS

(1) PPBS consists of premises, concepts and relationships

(2) System analysis consists of techniques attached to a way of approaching problems

b. It is application of benefit-cost analytical techniques to several areas of PPBS anatomy

C. PMMS -- Peat, Marwick, Mitchel Structure for Management and Reporting System (#24)

1. The highway safety program structure

a. Structure development

(1) Physical components classification

(2) Program phases classification

(3) Program elements

(4) Program sub-elements

(5) Program tasks

THE BUILDING PRINCIPAL'S ROLE

He realizes his own importance and his limitations.

He is aware that except for the classroom teacher no one has more direct influence upon curriculum improvement than the principal. Usually what he encourages takes place, what he neglects does not. Teachers cannot perform in the face of administrative indifference. At the same time, the principal knows he is not an expert in everything, and welcomes outside help in working with his staff.

He sets the tone concerning change.

He can accept innovation. He is not a "Don't rock the boat" man. He tries to see, moreover, that all those concerned with change are consulted about it. He helps the staff see the need for change, and to change. He contributes new ideas.

He supports the study committee.

Whether he is a member of the committee or not, he keeps informed on its progress. He helps interpret the committee's work to the faculty. He cooperates in attempting to provide materials, secretarial help, and released time for the committee. He recognizes and commends good work. He follows through.

He cooperates with other administrative and supervisory personnel.

He accepts other status staff members, whether from the superintendent's office, the county office or his own office, as partners in the program. He interprets his school and faculty to the other status personnel.

THE INTERMEDIATE ADMINISTRATOR

(The intermediate administrator is the title we have given to assistant superintendents, curriculum coordinators, county helping teachers, school vice-principals, supervisors, subject-matter specialists, department heads, or those of other titles who have status in between an institution head and the classroom teacher.)

He recognizes that his role may be misunderstood.

Some may not understand his job, or be in accord with his appointment to it. Some may resent him because his job represents authority;others because it may represent change which is threatening to them.

He asks the superintendent for a clarification of his role.

He wants to know what his job is, and what is expected to happen.

He recognizes his own importance and limitations.

He knows he has strengths which the committee may call for--in human relations, curriculum planning, administration, or in a particular subject area, as the case may be. He also knows his limitations, that he can't dictate particular policies to the committee, and that "keeping the peace" with other status personnel may prove difficult.

(c) Preparing objectives statement

(d) Identifying measurement parameters

- volume measures
- coverage measures
- effectiveness measures

(e) Selection of tasks and milestones

- types and sequence of tasks
- milestones
- schedule considerations
- task interrelationships

(f) Scheduling tasks and projecting measures

(g) Estimating and distributing costs

(h) Completing sub-element plan

e. Submission of annual work plan

(1) Reconciling SEP to total funding limitation

(2) Other forms to be submitted

(a) Program standards summary

(b) Objectives and priorities narrative

(c) Program-to-date-narrative

(d) Grant agreement

(3) Summary of AWP preparation process

D. CESEC -- Cost/Effectiveness System for Evaluation Counter Measures, by Operations Research Corp. (#19)

1. Need for cost/effectiveness evaluation

   a. Which corrective activities are most effective?

   b. At what level should each activity, ranked by importance, be undertaken?

   c. To resolve these issues, decision-makers must be able to formulate and evaluate alternative counter measure programs

2. The CESEC is a quantitative evaluation total and will improve the management of the entire safety program by:

   a. The existance of a formulized system will ensure that the developing state systems of analysis are properly directed and are compatable with the NHSB system

   b. The results of quantitative evaluation will be available at a level of detail most useful to the decision-makers.

   c. The flexibility of the system provides an extensive range of explorable "trade-offs."

3. Preferred program structure

   a. Synthesis of other alternative structures

   b. The major program categories recommended

      (1) Crash prevention

      (2) Damage amerlioration

(3) System restoration

(4) General support

(5) Research and development

E. ASF -- Highway Safety Program Management, 1968 (#16)

1. Use of Ideal Model to portray quality organization and management of highway safety programs

2. The "East Dakota" model

a. Organization of model program

b. Structure of model program

c. Manager outlines his duties

d. Sets forth role of committees in highway safety

(1) Proper use of committees

(2) When not to use committees

(3) Rules for overcoming disadvantages of committees

e. Operational procedures

(1) Secure statement of program's policy boundaries

(2) Gather facts

(3) Develop project proposals

(4) Assemble total program and establish priorities

(5) Implement program

(6) Report results

AD681521863

(7) Start again with step one

f. Measurement

(1) Application of measuring instruments

(2) Measurement requirements

(a) Indepth factual data on all elements

(b) "Yardsticks" for evaluating this data

(3) Several ways to implement measurement process:

(a) Working cooperatively with agencies

(b) Coordinating efforts through other agencies

(c) Form staff of specialists to carry out necessary duties

(d) Use of outside consultants to evaluate performance

g. Priority programming

(1) Determine total dollars available

(2) State-local division of funds

(3) Allocation between functions

(4) Select projects

(5) Test program against objectives

(6) Develop implementation schedule

F. HTSC -- Highway Traffic Safety Center, MSU, Model

1. Various systems have been developed by both public and private sector in an attempt to improve management of highway safety programs. This encompasses both organizational, administrative, and operational considerations.

2. The focus has in fact been on subsystems; thus, resulting in suboptimization entrapment and seriously limiting proper focus on the larger system, i.e., Highway Traffic Safety. The emphasis on the development of a "crash system" has resulted in a subsystem being given the treatment of a total system. Attempts are made to crowd all information and analyses from the total highway traffic system into the one subsystem or "crash involvement." The ultimate users of the system (Governor's representatives, etc.) then become frustrated when trying to implement noncompatable items, activities, or relationships.

3. There is a need, therefore, to design and develop other subsystems and build them into a comprehensive highway traffic safety system. The concepts on this system are:

   a. Collision control system

   b. Congestion control system

   c. Public services system

   d. Management system

4. This would supply information on needs and resources, provide techniques for predicting consequences of alternative programs, and provide control of the operational status of selected programs.

IV. Program Dimensions

A. Time

Time dimension consists basically of those aspects of a project relating to the time that each work element is expected to consume plus the total time for finalization of the project.

B. Cost

The cost dimension involves allocation of resources

C. Performance

The performance dimension refers essentially to levels of quality stated as end objective specifications.

V. Concepts of Program Structures

A. Display of major program and activity alternatives among which the department can choose to achieve its objectives.

B. Plays crucial role in identification, development, analysis, and choice of viable alternatives for pursuing objectives.

C. Because program structure provides the focus for analysis and decisions regarding alternative courses of action, it can significantly influence the evolution of a systematic plan to achieve departmental objectives.

D. Since effective management systems are evolutionary rather than a revolutionary process, there is no simple "correct" program structure for the government or a department.

E. Thus, a number of possible program structures exist at any point in time which change both in substance and appropriateness over time as the issues of concern to departmental managers change.

VI. Guidelines for Developing a Program Structure

A. Objectives orientation

D. Usefulness for management and control

1. If program structure is to serve as a management and control device, it must be capable of performing following functions:

   a. Facilitate current activity allocation

   b. Promote activity management

   c. Inter-relate the program and the accounting structure

2. Meaningful program structures will almost never correspond to organizational structures

VII. Project Management

A. Classic principles of organization

1. Nature of principles

   a. Unity of command

   b. Span of control

   c. Hierarchy

2. Validity as criteria for organizational design

   a. Method is obsolete

   b. Regidities encumber modern organization

      (1) Need to be adaptive

      (2) Need capacity for rapid response to rapidly changing environments, problems, and objectives

      (3) Capacity is optimized by organization

(2) Manager participates in and is responsible for development and operation of project through

(a) Planning

(b) Organizing

(c) Directing

(d) Controlling

c. Team is made up of people taken from several departments in the organization

(1) Members look to their parent departments for their continuing organizational identifications

(2) Results in many conflicts of interest

3. Problems associated with work-team forms of organization

a. Employees who want their work laid out for them precisely and who feel insecure without established procedures may find the work situation intolerable.

b. Shifting people from project to project may disrupt the training of new employees and impede the growth and maturation of specialists.

c. In the event of disagreement with department heads over the use of employees, the project manager must go to their common supervisor.

d. The project manager must act as a buffer between the frequent conflicting needs of his specialists and top management, without having the stabilized base of operation of the department heads.

e. The work-team approach is ineffective when the task at hand requires the coordinated efforts of numerous organizational elements and the coordinated efforts of numerous people.

4. Work-team approach to project management is not a panacea

a. Most effective when:

(1) Organization is large with diversified service

(2) Numbers of individual skill categories to produce a given service is large

(3) Large number of professionals are expected to exercise considerable discretion

b. A major disadvantage relates to effect of team approach on the informal organization

(1) Transitory status of members mitigates against development of enduring interpersonal relationships

(2) Can be counteracted by dedication to challenge of new assignment

THE LOCAL CHAIRMAN'S ROLE

He understands his task as committee leader.

He finds out from his superintendent or principal what is expected of him. He has a talk with the consultant to help clarify roles. He realizes he has a real responsibility to get something done. He analyzes his own strengths and limitations, including his own place in the school's power structure. He recognizes the importance of the involvement of teachers in planning.

He helps the committee to grow.

With the help of the consultant he gets his committee to identify the school district's own problems. With the help of the consultant he involves the teachers in a definite project. He gets to know the committee members and helps each to take on an appropriate portion of the total task. He leads them to discover their own needs, and their own talents. He makes suggestions, and welcomes ideas from others.

He does a communications job.

He maintains continual liaison among superintendent, principal, intermediate administrator, consultant, committee, and faculty. He arranges for consultant to have a chance to talk and work with committee members individually. He sends out notices of meetings and distributes materials ahead of time. He asks the committee to study and review its own procedures, and read materials on group process such as this Handbook.

He briefs administrators on committee progress.

He develops close understanding with the superintendent, who must fully grasp the committee's goals and progress in order to support the committee. He keeps in close touch with the building principal and intermediate administrator, who directly affect the conditions under which the committee works, as well as the prospects for real application of committee recommendations.

He does his homework.

He prepares an agenda for each committee meeting, even though he will not adhere to it rigidly. He keeps a file of everything pertinent to the committee. He sees that summaries are made of every meeting, duplicated, and distributed to all concerned. He expects his committee members to do their homework.

He understands the nature of change.

He personally feels comfortable with change and innovation. He is prepared, however, for some resistance to his committee's work. He knows that desirable and lasting change often comes slowly.

He follows through.

He does his best to see that agreed-upon tasks are completed on time. He reminds the superintendent or principal of previous commitments such as released time for his committee members.

2160

PART III

ELEMENTS OF HIGHWAY SAFETY PROGRAM

I. Key Events in the development of Highway Safety Prior to 1966

   A. First National Conference on Highway Safety (1924)

   B. Activity during the 1930's: the three E's

   C. White House Conference on Highway Safety (1946). Action program adopted

   D. Robert's Committee Held extensive hearings between 1958 & 1962.

   E. Ribicoff hearings of 1965

II. Federal Legislation of 1966

   A. Created a Department of Transportation which includes a National Highway Safety Bureau

   B. Passed a Motor Vehicle Safety Act

   C. Passed a Highway Safety Act

III. Standards as a prerequisite for control

   A. Primary factor for efficient control is accurate and up-to-date standards.

   B. Proper standards give management a workable yard-stick by which adverse variances may be detected.

   C. Origin of Standards

      1. Stems from managerial function of planning

      2. Goals are set and limitations or restrictions are identified.

      3. Standards then established in relation to these factors

D. Two basic but different catagories of standards

1. Independent standards

a. Not affected by variables

b. Value of standard is constant. Not affected by fluctuations in level of activity

2. Dependent standards

a. Affected by change

b. Have a positive or negative correlation to change in activity level

E. Standards enable management to:

1. Measure and evaluate the progress at periodic levels of activity.

2. Determine if the factor in question is above or below normal for a given level of activity.

F. In establishing standards following factors are considered:

1. Determination of what is the normal usage of x resources per given level of activity

2. What variables affect the standard as the level of activity fluctuates.

IV. Elements of the Highway Safety Program as Structured by the NHSB: History, Assumptions, Current Practices, Review of Effectiveness

A. Functional Elements

1. Periodic motor vehicle inspection

2. Motor vehicle registration and titling

3. Driver and Safety Education

21872

1. Program category designations should focus attention on activity objectives, rather than organizational position or resource composition.

2. Research activities are designated a separate program category because outputs do not lend themselves to quantification.

3. Same principle set forth above (2) applies to a general support category which involves joint-product, joint-cost items that cannot be assigned to other categories.

B. Trade-off orientation

1. Substitution

When two activities are directed to the same end, they are substitutes for one another, although the means,method or form by which they achieve that purpose differ.

2. Complementary

Activities grouped for analytical purposes because their close positive interdependencies mean that a change in the output of one will lead to a predictable change in the output of the other.

C. Unambiguous quantification of benefits and costs

1. First attribute that characterizes progress categories is that the benefit and costs associated with each category should be measureable in units that correspond to the arguments of the objectives.

2. Second attribute is that the program categories must be sufficiently distinct that benefits and costs generated by subordinate activities can be uniquely assigned.

(a) On a fluid work-team basis

(b) With project oriented teams:

- formed
- changed
- disbanded
- formed anew as work requires

B. Nature of work-team concept

1. Work-team design has existed in some form for some time

a. Project management

b. Product management

c. Program management

d. Task forces

e. Matrix management

2. Experience with work-team organization

a. Forerunners of the project manager

(1) Project expeditor: -- staff position concerned primarily with maintaining work schedules and removing work barriers

(2) Project coordinator: -- more formal role in organization, concerned with synchronization of activities directed toward specific objectives

b. Evolvement of project manager

(1) Due to work projects obtaining greater autonomy

4. Driver Licensing and Driver Improvement

5. Traffic codes and laws

6. Traffic courts (prosecution, adjudication, penalization)

7. Identification and surveillance of accident locations

8. Traffic records

9. Emergency medical services

10. Highway design, construction, and maintenance

11. Traffic control devices

12. Police traffic services

13. Accident cleanup

14. Accident investigation

B. Special Highway Safety Problems

1. Motorcycle safety

2. Pedestrian safety

3. Alcohol and Highway Safety

C. Services that support above elements

1. Public information and support

2. Highway safety research

3. Manpower development and training

V. Conceptualization of Highway Safety Programs

A. Highway Safety Program Areas

1. Education

2. Enforcement

3. Engineering

4. Legal

5. Service

6. Administration

B. Suggested Highway Safety Program Sub-Elements

1. General Traffic Safety Education

2. High School Student Driver Education

3. Adult Driver Education

4. Driver Improvement Education

5. Higher Education

6. Commercial Vehicle Operators Training

7. Trade School Driver Training (Commercial Vehicle)

8. Private School Driver Training

9. Traffic Law Enforcement

10. Alcohol and Drug Enforcement

11. Accident reporting and investigation

12. Traffic regulation and control

13. Motor vehicle inspection

14. Motor vehicle registration

15. Driver licensing

16. Conducting engineering surveys

17. Engineering design
18. Highway Construction
19. Highway Maintenance
20. Inspection of highways
21. Traffic law adjudication
22. Local codes and ordinances
23. State legislation
24. Accident Service
25. Aid to motorists
26. Public information
27. Non-governmental support
28. Bus transportation and safety
29. Research and Development

21876

PART IV

HIGHWAY TRAFFIC SAFETY MANAGEMENT

I. Nature and Purpose of Management

A. Definition of management

1. Desmond L. Cook (#13)

a. The art and science of planning, organizing, motivating and controlling human and material resources and their interaction in order to attain a predetermined objective.

b. According to Cook, management is broader than administration.

(1) Management focuses on process of decision making which is considered to be one of tasks of management.

(2) Administration focuses on implementation of policy and provision of administrative support to research programs.

c. Under this concept managers have line responsibilities while administrators have staff responsibilities.

2. Peter F. Drucker (#2)

a. Management is the specific organ of the business enterprise.

b. Management has partial rather than comprehensive social responsibility, hence partial rather than comprehensive social authority.

c. Management is a multi-purpose organ that manages workers and work.

d. Management is a rational activity.

(1) Means that organization must set objectives that express what is desirable of attainment.

(2) Rather than aim at accomodation of the possible.

3. Glenn Bassett (# 41)

a. Management involves at its core the ability to allocate resources of variable scarcity/ abundance in satisfying to the full needs of the organization, its clientele, its employees, and society as a whole.

4. Center for Safety Education, N. Y. Univ.

a. Traffic safety management is the application of sound management principles and practices to unified official programming for improved traffic movement and safety at national, state, and metropolitan levels. . . means of achieving the maximum results from coordinated planning and programming.

B. Purpose of management

1. To identify alternative forms of actions for making and implementing decisions in highway safety management.

II. Components of Highway Safety Management

A. General component groupings

1. POSDCORB (Acronym developed by Fayol)

a. Traditional grouping

b. Acronym coined in 1930 by Henry Fayol in his INDUSTRIAL AND GENERAL ADMINISTRATION.

c. Grouping consists of:

(1) Planning -- working out in broad outline the things that need to be done and the methods for doing them in order to accomplish the purpose set for the enterprise.

(2) Organizing -- establishment of the formal structure of authority through which work subdivisions are arranged, defined and coordinated.

(3) Staffing -- includes the whole personnel function of recruiting and training staff, and studying and improving working conditions.

(4) Directing -- consists of the continuous task of making decisions, embodying them in specific and general orders and instructions, and serving as the leader of the enterprise.

(5) Coordinating -- the all important duty of interrelating the various parts of the work.

(6) Reporting -- involves keeping those to whom the executive is responsible informed as to what is happening. This includes keeping himself and his subordinates informed through records, research, and inspection.

(7) Budgeting -- includes formulating the budget and performing fiscal planning, accounting and control.

2. POMC (Acronym developed by Department of Defense)

a. Component grouping currently recommended by federal government.

b. Grouping consists of:

(1) Planning

(2) Organizing

(3) Motivating

(4) Control

THE COMMITTEE MEMBER'S ROLE

He sees the need for curriculum improvement.

He knows that curriculum must change as society's needs change. He considers new ideas as challenges. He does not look upon suggestions for change as a reflection on his past performance.

He attempts to work as a group member.

He tries to understand the committee's purposes, and works to develop a "we" spirit among the group. He thinks before he speaks, and tries to put himself in the other fellow's shoes. He believes that the wisdom of the group is likely to be greater than that of any one of its members, but he is not afraid to make suggestions.

He tries to think impersonally and not defensively.

When he proposes an idea, he explains it but is not defensive about it. He is not hurt if the idea is torn apart or dropped; he treats his own ideas as he would anyone else's. He can accept advice from others, and invites the consultant to visit his classroom to observe experimentation.

He does his homework.

He realizes committee work should be divided up, and does his share. He gives of his own time, and expects the administrator also to allow him some time for committee business.

He acts as a missionary.

Without overdoing it, he interprets the committee's work to others among the faculty.

THE ROLE OF THE FACULTY MEMBER NOT ON A COMMITTEE

He can accept change.

He sees the need for the school to do something about curriculum revision. He does not consider change as a personal threat.

He recognizes individual differences.

He sees individual differences not only among students, but among teachers and administrators. He accepts himself, his fellow teachers, and his administrators as individuals who will each react to curriculum change in his own way.

He supports the efforts of a study committee.

He becomes acquainted with the needs of the total school system, not merely of his own level or department. He will listen to a study committee's report, make constructive suggestions, and be willing to put into effect adopted changes.

c. A management model utilizing this grouping is set forth in Figures 1 & 2.

B. Primary components of highway safety management

1. Planning
2. Organizing
3. Motivating
4. Coordinating
5. Funding
6. Evaluation

C. Other components in highway safety management

1. Budgeting
2. Cooperation
3. Staffing
4. Communication
5. Reporting
6. Policy formulation
7. Fact finding
8. Records
9. Training
10. Procedures development
11. Procurement of facilities and supplies
12. Research and development
13. Office administration

Figure 1

MODEL OF MANAGEMENT* PRACTICE

Plan

1. Forecast
2. Establish conditions and assumptions.
3. Establish objectives.
4. Anticipate possible future problems.
5. Establish policies.
6. Establish a program of accomplishment.
7. Plan standards and methods of measuring accomplishment.
8. Revise and adjust the plan in light of control results and changing conditions.
9. Coordinate ≠ throughout the planning process.

Organize

1. Identify and define work to be performed.
2. Break work down into operative duties.
3. Establish an ideal organizational concept.
4. Group operative duties into operative positions.
5. Group operative positions into manageable and properly related units.
6. Define position requirements.
7. Provide personnel facilities and other resources.
8. Revise and adjust the organization in light of control results.
9. Coordinate ≠ throughout the organizing process.

Motivate

1. Communicate and explain objectives and goals to subordinates.
2. Assign work to be performed, accountability, and extent of authority.
3. Assign performance standards.
4. Coach and guide subordinates to meet performance standards.
5. Train and develop subordinates to realize full potential.
6. Provide a motivating environment by communicating the changing situation and its requirements.
7. Praise and censure fairly.
8. Reward subordinates based on performance.
9. Revise and adjust the work of motivation in light of control results.
10. Coordinate ≠ throughout the motivating process.

Control

1. Review operations.
2. Compare results against goals (sub-objectives).
3. Appraise results against performance standards and policies.
4. Determine reasons for exceptions.
5. Record.
6. Revise and adjust control methods in light of control results.
7. Coordinate ≠ throughout the control process.

* Management is the vocation of achieving desired results through other people.

≠ Coordination is the consideration of relationships and/or utilization of activities outside a chain of command.

Source: R. J. House and J. M. McIntyre, "Management Theory in Practice," Advanced Management, October, 1961, (reprint, 8 pages).

III. Processes of Highway Safety Management

A. Decision-making

1. Definition

Decision-making is the process by which individuals and/or groups of individuals attempt to adjust their ideas and actions to outside factors which are believed likely to have influence on them. It may involve a personal action or an organizational one. It may be important or relatively consequential.

2. Complexity of the multitude of factors and forces operating in formation and implementation of decisions

3. Factors affecting decision-making

4. Analysis of the Process

a. Rather than looking to given standards of value and behavior, the new executive will be forced to rely on his self-created norms and interests in coping with change.

b. Action

(1) That aspect of decision making which a manager can most readily grasp

(2) Men of action have long been our acknowledged leaders

(3) Freedom is the indispensable condition to action

c. Choice

(1) All leaders know the anguish of choice

(2) The nature of choice

(a) Optimism -- Even in times of uncertainty, our choices are the best that seem possible. When goals beckon clearly, a person is most enterprising and resourceful.

(b) Open mindedness -- A manager must be prepared to alter his choices as he receives fresh information

(c) Empathy -- On the basis of subjective feelings of making choices, we also impute choices of others

(d) Alters personality of chooser

(e) Choices must be made among different ways to deal with limitations or barriers

(3) Awareness of freedom of choice

(a) Managers would engage in more creative acts if they were more aware of their elemental intent

(b) Laziness and pasivity cause a person to submerge freedom to choose in the unconscious

(c) This leads to a person becoming too secure, bored, and losing a sense of action

(d) This develops a habit of limited perception

(4) Code compliance

(a) Most pronounced in hierarchial organization where code seems to require different behavior for

(b) Manifested in a tenacious attachment to the system

(c) Concepts of cooperation and feasibility are invoked repeatedly to stifle deviant action

d. Objectivity

(1) Choice imposes on its practitioners a sense of objectivity

(a) An exact appreciation of where-I-am-now and how-I-am-to-get-there

(b) This requires a certain discipline in viewing one's impulses

(2) For the individual, objectivity means an understanding of the consequences of one's behavior

(3) For the organization, objectivity means a critical examination of the values and processes which have been created and maintained in its environment

(4) The enemy to true reality is ultrapracticality

(a) Managerial class has long given its homage to pragmatism

- method of prior formulation

- recurrent testing

- optimal decision making

(b) Such scientism is inevitably impersonal because models formulated for testing cannot encompass the complexities of people problems

(c) Hence, organizations tend to lose their rapport with people, i.e., their objectivity

(d) Thus, decision making is delegated to experts who frequently make the wrong choices

- expert's refuge and security is in rationalism

- when threatened by chaotic situation, he defines his terms, states his assumptions, applies his rigorous logic, and sticks by his conclusions by aloof superiority and catastrophic failure

(5) Following established rules may result in bizarre irrationalities because it suppresses recognition of nonroutine problems

(a) It is irrational to believe that administrators can conduct their affairs in same manner as scientists conduct research

(b) Because of its multidimensionality, there are few managers capable of considering the relationship and rationality of an organization's entire purpose pattern

(c) No matter what elements they may be concerned with, most managers develop a personal style of comparative weighting among desirability, feasibility, and consistancy

(6) Choice requires the manager to take risks which is endowed by a sense of commitment

e. Authenticity

(1) Primary quality of choice

(2) Involves behaving the way you are, instead of posing in a role

(3) Involves getting rid of irrelevant emotional garbage which is usually associated with the past

(4) It means honesty with one's self and directness with others

(5) It means telling it like it is

(6) An organization, like an individual is authentic to the extent that:

(a) Through its leadership it accepts its finitude, uncertainty, and contingency

(b) It realizes its capacity for responsibility and choice

(c) It acknowledges guilt and errors

(d) It fulfills its creative managerial potential for flexible formulation

(e) It responsibly participates in wider community

5. Developing your personal decision-making process

a. Organizational objectives

b. Organizations dynamics

c. Role of the individual

d. Problem areas

e. Improving human relations skills

f. Improving relationships

g. Relating decision-making to action

h. Defining organization's communications

21887

6. How decisions are influenced

   a. Typical patterns

   b. Various forces

7. Processes for insuring correct decisions

   a. Planning

   b. Review

   c. Research

B. How to improve desision-making process

1. Understand objectives

2. Know what is going on

3. Understand role of individual

4. Identify problem areas

5. Improve problem solving skills

6. Strengthen communications

7. Clarify relationship between decision and action

8. Improve operational relationships.

C. Planning Process

1. Definition of terms.

   a. A plan is:

      (1) a method or scheme of action

      (2) a decision made in advance of what is to be done

Figure 2

CLASSICAL MANAGEMENT THEORY IN PRACTICE*

*Source: R. J. House and J. M. McIntyre, "Management Theory in Practice," Advanced Management, October, 1961, (reprint, 8 pages).

b. Planning

(1) is the working out in broad outline of the things that need to be done and the method for doing them in order to accomplish the purpose set for the enterprise.

(2) involves a forecasting of the future problem and a scheme for meeting it.

(3) involves intellectual processes -- thinking before acting, and acting in light of the facts in an orderly way.

(4) involves the critical and exhaustive investigation or experimentation aimed at revising accepted conclusions in the light of newly discovered facts.

(5) involves a research attitude which requires that every statement, every principle, every pronouncement by oneself or by another be examined from two points of view.

2. General principles

a. Effective performance necessitates planning

b. Must organize to collect needed information to permit realistic planning and effective implementation

c. Create mechanism to collect and evaluate traffic safety related information

d. Conduct programs based on specific action plans

e. Locals should be involved in planning process of specific plans

THE CONSULTANT'S ROLE

He sets a tone.

He helps everyone clarify roles and uncover objectives. To do this, he must know his field, and know how changes take place in people.

He develops skill in listening.

He encourages group members to talk and react, and listens to each carefully. He is thus better able to discern problems and attitudes, and to be able to put himself in the other fellow's place.

He is a resource person.

He gives counsel to the local study committee. He helps them identify problems. He is not expected to know all the answers, but can advise and suggest alternate approaches. He locates reference materials for the group. He calls attention to new ideas. He talks to the faculty at the request of the local chairman. He visits classrooms to observe experimentation when this is helpful. He brings to the committee special knowledge and understanding. He acts as a sounding board for the ideas of others. He is willing to demonstrate procedures he advocates.

He works closely with the local chairman and other leaders.

He remembers that the whole thing is a team approach. He is particularly careful to become well acquainted with the superintendent, principal, and any intermediate administrators. He and they must clearly understand his role as consultant.

He does his homework.

Early in the process he learns a great deal about the district and its problems. If the committee needs certain information or background material, he finds it without delay. He anticipates the committee's needs whenever possible, and has information ready. He keeps in touch regularly with the area study council office.

He helps with evaluation and pushes for conclusions.

He acts as a sounding board for ideas. He helps the group to grow, and then to see how much they have grown. He helps the local group decide on recommendations and conclusions from its study and experimentation. He helps to draw the project to a close in reasonable time.

He adapts his role to the situation.

If things are not going well, or if a project seems to be floundering, he does something about it. For a time, he may have to take a more forceful role in direct leadership. While avoiding authoritarianism, he knows that sometimes he must become directive.

He has a professional dedication to his job as consultant.

He feels a responsibility to do the job well. He is willing to do more than his share of work to see the completion of the task at hand. He is concerned with upholding his own reputation and that of his college and/or council.

f. Professionals formulate plans but selected officials are responsible for implementation.

g. Plans should be in conformance with those of the adjacent jurisdictions to the greatest extent possible.

h. Areawide planning is more comprehensive and thus more efficient than fragmented planning.

3. Extent of planning

a. Trend appears to formalize planning with a special unit as size of operation increases.

b. This function is specialized when it exceeds the capacity of any single manager.

4. Importance of planning

a. Primary requisite to managerial functions of organizing, staffing, directing, and controlling.

b. Planning is unique in that it establishes the objectives necessary for group effort.

c. Primary function which manager must do before he can intelligently perform any of other managerial functions.

d. Plans provide basis for economical operation.

e. Good planning results in sounder decision-making at all levels.

f. Plans supply and emphasize the factor of adjustment among multiple interests, programs, ideas, specialties and pressures.

g. Plans give meaning and direction to action.

h. More efficient and more effective programs can only be developed as highway safety managers develop means of identifying and measuring underlying causes of highway traffic problems and then discover or create appropriate techniques to reduce these problems.

5. General Nature of Planning Process

a. Developing projects for getting things done.

b. Formulation and implementation of proposals based on facts.

c. Assists managers in discharging their responsibilities.

d. Charting of a predetermined course of action

e. Implies a wide consensus of opinion

(1) Steps to be taken

(2) Awareness of common problems

(3) Awareness of overall objectives

f. Perception of what exists today

(1) Available community resources

(2) Appraisal of needs and deficiences

(a) Financial

(b) Physical

(c) Manpower

g. Projection of long term trends in community development

(1) Rate of urbanization

(2) Public transportation facilities

(3) Population growth

(4) Highway construction

(5) Car sales

h. Serves four basic functions

(1) Identifies highway safety problems

(2) Provides factual information needed for administrative program

(3) Provides technical and financial information needed to implement highway safety resources

(4) Serves to stimulate further change

6. Process of Highway Safety Planning

a. Formulating objectives

(1) NHSB performance standards offer set of minimum guidelines

(2) Must have sound policy for

(a) Decision making

(b) Resource allocation

(c) Policy development

(3) Correlate program goals and resources available to accomplishment of objectives

b. Data collection

(1) Conduct detailed inventory

(a) Necessary to discover and eliminate deficiencies

(b) Needed to establish program priorities

(c) Needed to project cost estimates

(2) Functional inventory useful technique

(a) Focuses on safety activity

(b) Once facts are accumulated it facilitates evaluation

(3) Search of law and legal authority

(a) Laws creating and regulating agency

(b) Laws affecting behavior

(c) Collate traffic law with UVC

(d) Compare state's model ordinances and local code

(4) Develop fact gathering guide

(5) Conduct surveys

(6) Sources of information

(a) Accident records and reports

- Key to information system
- Basic tool for management
- Core of planning activity
- Must be based on facts

(b) Community disaster plans

- Contingency plans
  - . Based on local features of environment
  - . Geared to probable danger areas
  - . Take into account factors of:
    - Traffic volume patterns

- Location of hospitals
- Other emergency installations

c. Identification of problems and needs

(1) In light of local condition

(2) In terms of current technology

(3) In terms of the national standards

(4) In terms of available resources

(5) Identification techniques

(a) Formulation of accident review committee

(b) Other methods

d. Developing plan

(1) Should provide complete strategy to be followed in reaching objectives

(a) Citing specific responsibilities of each component of organizations staff

(b) Describe functions of specific anchillary groups and private organizations concerned

(c) Set forth time schedule of priorities

(2) Spirit of cooperation is essential to process

(3) Priority consideration a basic factor in plan development

e. Plan implementation

(1) Plans are implemented when they become

(a) Official policy

- Adopted by local legislatures and executes those various kinds of legal procedures

  . Administrative rulings

  . Policy statement

  . Legislative enactments

  . Ordinances

(b) Operational

- Elected officials responsible for putting plans into action

f. Plan evaluation

(1) Competent evaluation will facilitate plan modification

(2) Evaluation procedures should determine

(a) How far has plan progressed towards stated objectives, within time frame given

(b) What improvements are needed to make plan more effective

(c) What program needs can be anticipated during next evaluation period

(3) Adoption of conceptual yardstick or standard

(a) Equate performance to cost

(b) Calculate and compare various returns on investment

- Outline various program objectives that can be acheived by:

  . Alternate means

  . For the same cost

g. Updating plan to improve its effectiveness

7. Anatomy of planning

a. Activities of planning

(1) Forecasting

(2) Establishing objectives

(3) Programming

(4) Scheduling

(5) Budgeting

(6) Establishing procedures

(7) Developing policies

b. Characteristics of plans

(1) Good plan is based on clearly defined dimensions and objectives.

(2) It is as clear and simple as subject matter will permit.

(3) It has stability while providing for flexibility.

(4) It outlines standards of operation and clearly provides for them.

(5) It is economical in terms of resources needed for its implementation.

(6) It meets a real need and anticipates the future.

(7) Plans should be made in terms of total situation.

(8) Plans should provide for continuous review and evaluation.

c. Types of administrative plans

(1) Figure 3 depicts types of plans

(2) Figure 4 sets forth key questions to guide the extent of planning.

d. The planning process: - Suggested steps or units as a comprehensive guide.

(1) Need determination

(2) Objective

(3) Preparing proposal

(4) Obtaining approval proposal

(5) Organizing for planning

(6) Determining specific outline of plan

(7) Establishing contact with cooperating groups

(8) Obtaining necessary data

(9) Evaluating the data

(10) Formulating tentative conclusions and preparing tentative plans

(11) Testing components of tentative plans and making adjustments

(12) Preparing the final plan

(13) Testing plan

(14) Obtaining approval of plan

Figure 3

TYPES OF ADMINISTRATIVE PLANS*

Scope	Goals	COURSES OF ACTION	
		Single-Use Plans	Standing Plans
Broad Plans	Objectives (Missions)	General Programs	Policies
	Budget and Deadlines	Projects	Organization Structure
	Performance Standards for Expense, Quality, Quantity, etc.	Personnel Assignments	Standard Procedures
Detailed Plans		Detailed Schedules, Specifications, Methods, etc.	Standard Methods

*Source: W. H. Newman, Administrative Action (second edition; New York: Prentice-Hall, 1963), p. 53.

Figure 4

QUESTIONS AN EXECUTIVE SHOULD ASK HIMSELF ABOUT PLANNING*

Key Questions Guiding the Extent of Planning

Single-Use Plans (Programs, projects, detailed specifications, schedules, and the like)

1. Will the plan help to get the right man at the right place at the right time, adequately supplied with instructions, materials, and equipment; instead of "too little, too late"?

2. Will the plan improve coordination of several activities?

3. Will planning lower costs or increase effectiveness of the activity, through
   a. anticipating trouble, and
   b. developing more efficient methods?

4. Will planning ease the load on hard-worked executives by
   a. permitting more decentralization of authority to act, and
   b. providing guides for use in control?

5. To what extent is detailed planning warranted by the reliability of forecasts of operating conditions?

6. Will planning in advance lead to unwise commitments?

7. Will executives continue to be alert to new conditions and quick to adapt their actions to them?

8. Is the activity important enough to warrant formal planning? Will the improvement in results be worth more than the added expense involved in additional planning?

9. Is there time for detailed planning, or is prompt action more important?

10. Will the planning capitalise on the abilities and ideas of individuals throughout the enterprise and build morale?

32 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

Standing Plans (Policies, standard methods, standard procedures, and the like)

1. Can administrative work be simplified by adoption of plans that will be used over and over again?

2. Will efficiency be improved by intensive study to discover the "one best way", and by insistence on the use of such standard methods and procedures?

3. Is uniformity of action important, and will standing plans help to achieve it?

4. Will standing plans ease the load on hard-worked executives by
   a. permitting more decentralization of authority to act, and
   b. providing an established behavior pattern to use in appraising action of subordinates?

5. Will use of standard methods simplify training and permit use of less experienced workers?

6. Is the repetition in operations significant enough to justify the effort involved in making standing plans?

7. Can operating conditions be controlled closely enough to make detailed standard methods feasible?

8. Will the expense of preparing the plans and enforcing them more than offset the benefits?

9. How serious is the inflexibility that will arise? Can provision be made for prompt modifications and exceptions when they are needed?

10. Will insistence on standing plans have a bad effect on individual initiative?

Goals (Objectives, missions, deadlines, performance standards, and the like)

1. Are the efforts of executives ineffective due to lack of clearcut objectives?

310 OF 327

ED

056 238

D-55

4. Are plans be prepared here mainly by identifying which, problems, and questions?

5. Will the planning process be made easier and more realistic if the planning commission and the city council meet jointly to develop goals to recommend?

6. Will valuable time be saved (problems identified) by preparing a list of problems and questions?

7. Will problem statements be improved by providing standards for measuring them?

8. Will current resources be more realistic and efficient if the planning commission meets jointly with the city council?

9. Will the planning commission process be valuable enough to justify the additional effort?

10. Will the process of identifying goals be greater than the process of identifying problems?

11. Will the goals have to be changed as time goes because of changes in the community? Will the process be valuable enough to justify the effort?

12. Will the problems or goals need just to be reviewed or revised periodically and continued or dropped?

Source: "A Guide to Comprehensive Municipal Planning", Illinois Institute for Environmental Quality, Chicago, Illinois, 1972, pp. 55-56.

D-56

6. Implementing the plan. -- Factors that enhance the implementation:

(1) Issues in approved plan

(2) Strategies to implementation of feasibility; Implementation strategies

(3) Institutionalization of identification of plan

(4) Determination of role of implementation

(5) Prioritize implementation steps and relationships

(6) Adaptation of the implementation plan

(7) Taking action and making necessary commitments

(8) Establishing implementation schedule of the program

(9) Determination of operational plans to implement the program

(10) Initiation of undertakings in order (actual) documents

(11) Ordering data on progress in plan

D-57

(1) Complexity

(2) Significance

(3) Scope of expenditure

(4) Commitment

(5) Responsibility

(6) Authority

(7) Incentives

(8) Motivation

(9) Flexibility

(10) Available time

(11) Intelligent action

(12) Coordination

(13) Resources

(14) Capacity

(15) Adjustment

D-58

(2) Potentially just have significance.

(3) Questions that might be posed:

(a) What are the goals for public sector financial investment efforts over the next decade?

(b) What is the impact of the use of private planning consultants upon the implementation process?

(c) What are the effects of capital financing upon the implementation process?

(d) What are the impacts of federal financial aids upon the implementation process?

(e) Are the goals of the planning process have been the planning process have been the planning process?

(f) What impact does the implementation process have upon the planning process?

D-59

2. Assess in understanding the problems and opportunities of the community and how plans relate to meet future:

Analyzed in terms of planning and implementation.

Analyzed in development functions (see text) by the development of new functions and priorities.

B. Evaluation

1. Search background:

a. Most important criteria element of highway analysis

b. Program evaluations be difficult to measure but a most important process

(1) Inadequate evaluation has resulted in:

(a) Negative consequences of program

(b) Inadequacies of expensive but ineffective programs

D-60

(2) Models: (see Dunham, Alexander Pas text) Models of evaluation of a well planned or poorly planned program.

(3) Are you in the business of identifying (or evaluating) the relevant (identifying) [illegible]

(a) Problem

(b) Objectives

(c) Data (evaluation) will be used to use of the data process

c. Expenditure Indicators of evaluation

(1) Evaluation can be of long programs or short programs (see Alexander Pas text)

(2) Evaluation is an attempt to measure:

(a) Impact objectives: need to define the impact objectives

(b) Process objectives: Statement of the process of the program (specific activities) (specific data) (data) (data) (

- Thus, Proximate, rather than ultimate tests have to be used no matter what problem or choice might be considered.
  - opens door to erroneous criteria
  - problems of choice must be broken down into component pieces or subproblems
- Inherent danger that criteria adopted in lower-level problems may be unrelated to higher-level criteria.
- Common criterion errors
  - Maximizing gain while minimizing cost
  - Overlooking absolute size of gain or cost
  - Setting wrong size of gain or cost
  - Neglecting spillovers
  - Using wrong concepts of cost or gain
- Breakdown of problems makes some aspects of analysis more manageable and has some advantages.
  - Suitable criterion forms
    - Maximum gains minus costs
    - Either gains or costs fixed

(b) Working definition of criterion

- test of preferredness

(c) Stages of applying criteria

- Determining options

- Determining feasibility
  - An important criterion once you have the options in hand is to determine how the device or method will fit the situation as it presently exists. Usually this requires three considerations be studied to predict whether or not a solution will fit.
    - Is it technically compatible?
    - Is it culturally compatible?
    - Is it economically sound?
- Devise an installation plan
  - Start at the beginning and follow through a step-by-step projection of the application of the option.
  - Predict obstacles and devise methods for overcoming them
  - Allow for contingencies

(d) Criteria as Measurement

- Measures of terminal objectives are referred to as "ultimate criteria."
- Measures of enabling objectives are termed "intermediate criteria."
- Both may vary in terms of their reliability and validity.
- Most prevalent practice has been to measure levels of accomplishment either on intermediate or ultimate criteria, and then, ex post facto, attempt to determine if these levels of accomplishment can be accounted for in terms of past program experience. This practice has yielded, at best, equivocal results.

- Means of supervision and control over matters that require services to public by assuring that all departmental resources and information is focused on each case.
- Focal point of analysis of all reports that are submitted in departmental operations.
- Report review is function of supervision
  - Quality of system is primarily dependant upon supervisor's review of reports.
  - Report review is vital aspect of management.

3. Practice Session for Students to Develop Evaluation Tool

   a. Distribute and explain bedsheet model.

      (1) Objective

      (2) Measure of effectiveness

      (3) Criteria

      (4) Tasks and Milestones

   b. Divide students into working groups.

      (1) Distribute worksheets

      (2) Assist students with the development of an evaluation plan of their own choosing.

IV. Nature of Management Objectives

A. Enables us to do five things.

1. To organize and explain the whole range of phenomena in a small number of general statements.

2. To test these statements in actual experience.

3. To predict behavior.

4. To appraise the soundness of decisions when they are still being made.

5. To enable practioners to analyze their own experience and as a result improve performance.

B. Areas of performance objectives

1. State of the art

2. Innovation

3. Productivity

4. Physical and financial resources

5. Profitability

6. Manager performance and development

7. Worker performance and attitude

8. Public responsibility

C. Determining objectives for:

1. Manager performance and development

   a. Direction of manager and self control

   b. Setting up of jobs

   c. Spirit of management

   d. Structure of management

   e. Development of new managers

2. Public responsibility

   a. Set according to social and political conditions

   b. Set by beliefs of each manager

2. Can plans be dovetailed more easily by identifying goals, sub-goals, and sub-sub-goals?

3. Will the planning process be made easier and more reliable by development of many detailed standards which can serve as building blocks in programming?

4. Will activities that do not contribute significantly to basic objectives be recognized and curtailed?

5. Will personal incentive be improved by providing standards of achievement?

6. Will control activities be more realistic and effective by closely relating planning with control standards?

7. Will prediction and internal control be reliable enough to make the goals really valid?

8. Will the benefits of having clear goals be greater than the added expense of preparing them?

9. Will the goals have to be changed so often that confusion and frustration will result, rather than improved morale?

10. Will the statement of detailed goals lead to unwarranted advanced preparation and reluctance to change?

*Source: W. H. Newman, Administrative Action (second edition; New York: Prentice-Hall, 1963), pp. 72-73.

(1) Complexity

(2) Significance

(3) Scope or magnitude

(4) Comprehensiveness

(5) Frequency

(6) Duration

(7) Uniqueness

(8) Authorization

(9) Flexibility

(10) Available time

(11) Confidential nature

(12) Clearness

(13) Formality

(14) Specificity

(15) Completeness

(16) Accuracy

(17) Stability

c. Manner in which a given function is planned and then put into operation may be influenced by the intensity with which dimensions occur.

d. Impact of dimensions.

(1) Important to know relationships between dimensions and the processes.

(a) Observe a variety of plans differing in the intensity with which dimensions occur and record the variations.

21903

(b) Formulate and test hypotheses.

(2) Questions that might be posed.

(a) How does the need for highly confidential information affect the planning process?

(b) What is the impact of the use of outside planning consultants upon the implementation process?

(c) What are the effects of central planning upon the implementation process?

(d) What is the impact of highly technical plans upon the non-technically trained approving agent?

(e) What impact does the frequency of planning have upon the planning process?

(f) What impact does the uniqueness of a plan have upon the implementation process?

(g) What impact does loosely defined objectives have upon the planning and implementation processes?

9. Planning-Implementation model can serve at least six purposes.

a. Assist in understanding <u>how</u> the management process is carried out in all kinds of organizations.

b. Assist in understanding <u>why</u> the process is carried out in a certain manner.

c. Assist in determining the <u>results</u> that are likely to be achieved from following a given process.

(2) Usually the funding allocated for evaluation when using the above approach is a small percent of the total project.

(3) If we are to resolve the problem, the approach has to be changed drastically, i.e.,

(a) Program

(b) Evaluation

(4) Thus funding for evaluation will be equal to that of the total project

c. Fundamental Principles of evaluation

(1) Evaluation can be of total programs or it can focus on aspects of programs

(2) Objectives are stated in several ways

(a) General objectives:- used to define aims and scope of program

(b) Terminal objectives:- Statements of more specific intended outcomes articulated at the levels required for their effective use in the real world.

(c) Enabling objectives:- Statements of intended outcomes which are:

- either meaningful components of the outcomes specified under terminal objectives,

- or outcomes which are believed to be essential background inputs for the terminal objectives.

d. Forces supporting comprehensive evaulation

(1) Requirements of federal standards

d. Assist in understanding the planning and implementation needs of an organization and thus guide managers in their efforts.

e. Assist in auditing a planning and implementation process.

f. Assist in developing hypotheses that will lead to the development of new theories and principles.

D. Evaluation

1. General Background

a. Most important missing element of highway safety

(1) Program evaluation is difficult to achieve but a very important process

(2) Inadequate evaluation has resulted in

(a) Negligible innovations in highway safety programs

(b) Perpetuation of expensive but ineffective programs

b. Evaluation in perspective

(1) We have continuously tried to make evaluation a small subpart (component) of operations. This is why it has not been mastered, i.e.,

(a) Plan

(b) Assess

(c) Control

(d) Evaluate

e. Implementing the plan: -- Factors that concern the implementor.

(1) Receipt of approved plan

(2) Obtaining an understanding of technical components of plan

(3) Interpretation of ramifications of plan

(4) Determination of role of implementor

(5) Organizing implementation staff and assigning responsibility

(6) Preparation of an implementation plan

(7) Taking action and making necessary commitments

(8) Notifying organization member of the program

(9) Interpretation of operational plans to affected subordinates.

(10) Instruction of subordinates in their control assignment

(11) Gathering data on progress of plan

(12) Review and evaluation of plan

(13) Taking corrective action when necessary

(14) Reporting progress to authorized personnel

8. The dimension concept.

a. Helps planner understand the nature of the variations occuring in the planning and implementation process as different activities are considered.

b. Seventeen dimensions characterize either the planning process or the implementation process.

(2) Money available for evaluation projects

e. Barriers to achieving comprehensive evaluation of highway safety programs

(1) Program management not sold on importance of evaluation.

(2) Program management does not consider evaluation as priority measure

(3) Insufficient numbers of professional personnel to do evaluations

(4) Need for training programs in evaluation

(5) Determining valid evaluation methods for highway safety programs.

2. Nature and characteristics of evaluation

a. Consists of two broad areas.

(1) Assessment: determine state of the art; the amount, extent, etc.

(2) Analysis: interpretation of findings.

b. Nature of assessment

(1) National Safety Council field surveys.

(2) Highway Traffic Center, M.S.U., Questionnaire Method Testing study as example of self assessment and attempt to validate same.

(3) Univ. of Michigan, Highway Safety Research Institute, Study to develop methodology for program evaluation.

c. Nature and Use of Analysis in Evaluation of highway safety

(1) Role of analysis in economizing

(a) Careful analysis in many instances leads to increased output or a larger pay off.

21907

CHAPTER VI

Finishing the Job

Implementing change is essential,
but the process of changing
is really never finished.

"Whatever happened to that report?"...."Didn't we have a committee that worked on that a couple of years ago?"...."Whatever happened to Committee X? We never heard any more about it."..."I'm not getting on another committee. I put all that time into the last one and nothing was done about our recommendations."

Do these sentences sound familiar? Unfortunately, many teachers have heard or said them. They reflect a tendency in some school systems to fail to set reasonable target dates or deadlines for action.

This chapter is intended to help those who are involved in curriculum study to make the kind of evaluation and reports that tend to get attention and action. As just implied, action generates more action. Inaction breeds disillusionment and discontent. What is done as a result of one curriculum study affects not only that study, but the curriculum development hopes of a school for the future.

Mere action, of course, is not enough. Only carefully prepared, responsible recommendations are likely to be considered by an administration or Board of Education.

2163

(2) Usefulness of analytical aids

(a) Use of the model

(b) Operations analysis

(c) Systems analysis

(d) Quantitative analysis

(e) Qualitative analysis

(3) Problems of analysis

(a) Problems stem from obstructionist nature of real world and not from tools of research

(b) Difficulties are present when choices are made whether decisions are based on systematic analysis or irrelevant assertions

(4) Role of Criterion (#37)

(a) Criterion selection problems

- Good intentions (goals) do not always pave the way to preferred action

- In choosing alternatives we also adopt criteria or tests of preferredness

- Criterion problem could swallow up all aspects of the comparison of alternative courses of action

- Problem of deciding what consequences decision-maker should know about

- In practical problem solving we have to look at some "Proximate" criteria which serve to reflect what is happening to product

MICROCOPY RESOLUTION
NATIONAL BUREAU OF STAND

TEST CHART
NDARDS-1963-A

(5) Measuring costs and benefits

(a) Cost-benefit analysis functions as a tool to assist management in its attempt to optimize use of available funds.

(b) Potential benefits of project can be predicted and evaluated.

- Because of a reasonable degree of certainty as to its extent and impact

- Because of relative short time span between performance of research on project and implementation of results

- Improvements in working conditions create benefits by increasing quality of work environment

(c) Types of project costs and benefits

- Direct benefits and costs

  . Increases in production of goods and services

  . Marginal benefits must equal or exceed marginal costs.

  . Direct benefits are net benefits of the incremental output associated with a specific alternative, not the net difference in benefits between the superior and the next best alternative.

- External or "spillover" effects

  . Pecuniary spillovers

  . Technological spillovers

- Secondary benefits and costs

  . Expansionary effects of project's direct benefits

21911

- . Differ from external benefits and cost in that they are compensated shifts in economic resources

- Intangible benefits and costs

  - . Those project effects which are unmeasureable in any objective and generally accepted terms

  - . Actually, number of completely intangible effects may be very limited.

  - . Avoid tendency to overload this category.

- Incommensurable effects

  - . Cannot be neatly categorized

  - . Are intangibles that can be quantified by "at least" method and submitted in section along with other qualitative aspects.

- Prescribed benefits

  - . When made explicit project goals, they must be quantified to degree practicable.

(d) Relationship of standards to cost-benefit

- Standards serve to internalize previously external costs.

- Such costs are quantified and become subject to profit and loss calculations.

- Therefore, when standards exist, the entailed costs necessary for compliance are available.

- As standards are revised, they may change previously computed benefits and costs.

(6) Other measurement and evaluation concepts

(a) Cost-effectiveness system for evaluation of accident countermeasures (#19)

- Individual components

  . Effectiveness model

    Estimates the anticipated reduction in mortality, morbidity, and property damage owing to the implementation of a new standard, or a change in the level or implementation of an existing standard.

  . Cost Analysis Model

    Estimates the total system costs generated by implementing a new standard or changing level of implementation of an existing standard.

  . Allocation Model

    Determines on a cost-effectiveness basis the best mix of the standards being considered (by NHSB) and the expenditure level for each standard to achieve a maximum reduction in mortality, morbidity, and property damage subject to specified resource constraints.

- Provides insights into "trade-off" questions.

  . Given a budget to be allocated among alternative standards, what is the greatest reduction in deaths, injuries, property damage, or some combination thereof, that can be achieved?

  . Given a desired reduction in deaths, injuries, property damage, or some combination thereof, what is the smallest budget that can be allocated among alternative standards to achieve such a reduction?

(b) Program evaluation and review technique

- PERT/COST System
- Resource allocation
- Time cost
- Implementing PERT
  - . At time of proposal (planning)

(7) Administrative review

(a) Personnel review

- Evaluation of performance
  - . Quantification of qualitative criteria
    - <u>Nature of quantification</u>
      - . Roger Bacon said that knowledge wasn't scientific until it used numbers.
      - . Sir Francis Galton, who launched the modern theory of statistics, suggested, "Whenever you can, count."
      - . For managers, numbers are an important tool for thinking and problem solving. Problems that seem vague and unmanageable come into sharper focus when you can count and compare.
    - <u>Measuring the Unmeasureable</u> (#7)
      - . (See Figure 5)
        - When quantification is not built in.
          - . Assignment of values

Figure 5

MEASURING THE UNMEASURABLE

1. It is often necessary to devise measurements of present levels in order to be able to estimate or calculate change from this level.

2. The most reliable measures are the real time or raw data in which the physical objects involved comprise the measures to be used (dollars of sales, tons of output, number of home runs hit).

3. When raw data can't be used, an index or ratio is the next most accurate measure. This is a batting average, a per cent, a fraction or a ratio.

4. If neither of the above two can be used, a scale may be constructed. Such scales may be "rate from one to ten," a nominal rating against a checklist of adjectives such as "excellent, fair, poor," or one which described "better than" or"worse than" some arbitrary scale. (These are useful but are far less precise than the above.)

5. Verbal scales are the least precise but can be extremely useful in identifying present levels and noting real change. Verbs such as "directs," "checks" and "reports" are indicative of actions to be taken.

6. General descriptions are the least useful, but still have value in establishing benchmarks for change. "A clear, cloudless fall day" is obviously not the same as a "cloudy, foggy, misty day" and the two descriptions could be used to state conditions as they exist and conditions as they should be.

7. The statements of measurement should be directed more toward results than toward activity. (Much activity may prove impossible to state in specific terms, whereas results of that activity can be stated.)

8. In stating results sought or in defining present levels, effort should be made to find indicative, tangible scales, ratios or raw measures where possible.

9. If you can't count it, measure it, or describe it, you probably don't know what you want and often can forget it as a goal.

(b) Management review (#9)

- Assess your job for changes in responsibility and activity

  . Be practical. Look at longer-range perspective. You will win a few and lose a few.

  . If dissatisfied, tackle problem of self-scheduling from scratch.

- Reconsider important problems from time to time.

- Periodical review of progress in order to make sure original objectives will be achieved.

- The Managerial Grid approach to management review. (Dr. R. Blake & J Mouton, U. of Texas)

  . Managerial Grid approach has two basic premises:

    - A manager can be measured according to two variables:

      . concern for people

      . concern for production

    - The best management is team management

  . Nature of the Managerial Grid

    - "Concern for people" is measured vertically on line divided into nine sections.

    - "Concern for production" is measured horizontally on line similarly divided.

Figure 6

MANAGERIAL GRID

EVALUATING THE COMMITTEE'S WORK

Real evaluation of a committee's efforts and findings often fails to take place. We never really know if the work was worthwhile. How do we find out? We must examine our efforts as we go along, and again after the job is completed.

Sitting in Judgment

A regular part of every meeting of a curriculum committee should be used for a quick checkup. How are we doing? How do we know?

This means we ask ourselves:

What did we set out to do?

What sub-goals did we set?

What have we accomplished?

Where are our strengths?

Where are our limitations?

What should we continue?

What should we do differently?

This needn't be as time-consuming as it appears. The focus can be on short-range goals that were set up as targets for each meeting.

Getting the Habit

The habit of evaluating is a vital habit. Why? Because it:

Provides sureness of focus on the real problem.

Stresses the accountability of the committee.

Provides "feedback" of ideas to correct errors.

Promotes more effective long-range evaluation.

This practical experience of making judgments within the committee--and learning to take criticisms from others in good grace--will make members more sensitive to criteria for reporting the final evaluation.

Tangible Evidence

Any committee should try to set some goal, however small, that lends itself to tangible evidence of achievement. Committee members and others can scoff at testimonials and feelings about success, but they cannot laugh off hard evidence.

What, specifically, could be used as tangible evidence? Here are some examples:

Test scores that show progress in skills or subject-matter beyond that normally expected.

Statistics that show increases in whatever behaviors the committee set out to increase.

Pictures--before and after--when they are relevant to the studies undertaken and when they are honest comparisons.

A study committee should think about the evidence that would reflect achievement of committee goals when it starts work. It may be too late to collect comparative data later.

Don't Stop

Evaluation should not cease with the "final recommendations" of the committee. It should continue for at least a year in order to see if changes really take place. Perhaps the same committee, already familiar with the problem, should continue in existence. The task of curriculum building is never really finished.

References

Amidon (3) and ASCD 1948 (5) provide ideas on evaluation.

- Resulting Grid has 81 positions which can be used to delineate various styles of leadership.

. Management styles depicted on Grid

- Task management: Lower right hand corner of grid portrays this style, i.e., 9.1 management. It is characterized by strong emphasis on task to be performed. People are of little consequence. Strict authoritarian type of leadership. Results in subordinates losing initiative; creative approach to problems; increased skill remains untapped. Consequence is gradual shift of managerial persons in direction of 1.1, accomodation.

- Country-Club management: Located at 1.9 in upper left-hand corner of grid. Opposite of task management. Emphasis all on people. Production suffers at the expense of harmonious relations. When called upon to increase efficiency frequently unable to respond. Tends to succomb to competitive pressures.

- Impoverished Management: Located at 1.1 in lower left corner of grid. Couples low concern for people with low concern for production. Just enough to get by. Leads to deep frustration and discouragement. Situation of a failure.

21919

- Represent a difference in elements by weighting.
    - Element A=50%
    - Element B=25%
    - Element C=25%

- Rating Scale
    - Instead of numbers make comparisons by use of graded scale e.g.,
        - Excellent
        - Good
        - Fair
        - Poor
        - Unsatisfactory
    - Objective is to make your thinking more specific. By avoiding vagueness you sharpen the facts and make possible comparisons that are helpful for evaluation.

- Check on progress
    - If task is not simple and clearcut, it may be desirable to keep in touch with developments.

- Evaluate achievement
    - reward achievement
    - review aspects of job
    - progress review is a running evaluation of plan. Much to gain in a retrospective view.

- Dampened pendulum management: Located at 5.5 in the center of the grid Manager aware of conflict between people and production and tries to effect a compromise, Real problems are apt to be muted and climate is frequently paternalistic. Has limitations; provides a poor base for promoting innovation, creativity, discovery, and novelty. These sacrificed by adherence to tradition and "majority" standards of conduct. Results in status quo, a gradual slipping behind.

- Team management: Upper right hand corner 9.9 sets forth obvious goal of good management. High concern for both people and production. In short, "the needs of individuals to be engaged in meaningful interdependent effort mesh with the organization requirements for excellent performance."

. Management Grid is a tool to help analyze one's managerial style, the styles of other managers, or the total management of a company. Its a way of structuring one's thinking about styles of management, and as such, both an analytical and constructive tool.

(c) Program or Project review

- Report review

. Obtain progress reports for information and control purposes.

C. Span of control vs. span of managerial responsibility

1. Latter is wider than former.

2. Latter reduces temptation to supervise, that is take over the job.

D. Authority and responsibility

1. Authority should be task oriented

2. Setting limitations on authority

a. All authority not expressly reserved for higher management is granted to lower management.

VI. Management Responsibilities of Government Official

A. Highway Safety Act of 1966

1. Public Law 89-564

2. Administered by NHSB of DOT

3. Purpose

a. Provide assistance to state and local gov'ts. for improvement and expansion of highway safety programs in accordance with standards issued by Secretary of Transportation.

b. Act specifies requirements relating to program administration, program areas to be implemented and formulation procedures of performance standards.

4. Funding -- grants and aids

a. Section 402: grants-in-aid

b. Section 403: research and development funds

5. Act provides mechanisms for coordinating highway traffic safety programs.

a. Throughout the nation

b. Created state programs directed by governors' representatives

c. Logically should be applied at local level in form of individuals or committees

B. Primary responsibility for highway safety programs is invested in governor's office.

1. Each state enacted specific provision conforming to federal requirement.

2. Some states created an office of state highway safety coordinator within the governor's office.

3. Some states have created an official state body to assist the governor's representative in developing priorities and promoting a statewide program based on local needs.

a. Official traffic safety commission

b. Highway safety study committees

c. Highway safety advisory committees

4. Function of state safety commission, advisory committee and coordinator

a. Organize, plan and conduct a statewide highway safety program

b. Coordinate and supervise activities and programs of the several agencies engaged in promoting highway safety

c. Provide highway safety information and publicity to all appropriate media and develop other means of public information

d. Cooperate fully with all national, local and public and private agencies and organizations interested in promoting highway safety

e. Serve as clearinghouse for all highway safety materials and information

f. Cooperate in promoting research, studies, and analyses of problems concerning highway safety

g. Make studies and recommendations to legislature concerning safety regulations and law

h. Prepare and submit annual report to governor re activities of Commission

i. Basic responsibilities of coordinator

(1) Define objectives

(2) Coordinate and balance resources

(3) Provide leadership and liaison between local-state departments of government and independent agencies

(4) Assist local programs to conform with state and national standards

(5) Monitor program development

VII. Management at Local Level (#28, 29, 32, 33)

A. Primarily a local responsibility

1. Statistical data on crashes

a. Deaths and injuries

b. Costs

2. Analysis of problem

a. Responsibility for local traffic program difficult to identify

b. Almost impossible to hold anyone accountable for results at local level

c. Many agencies at local level duplicate efforts of others, thus overlapping functions and costs.

d. Non-government organizations also are involved in projects.

e. Need for program coordination at local level.

3. Responsibilities related to program standards

a. Must deal with each functional standard

b. Will vary from standard to standard

c. Must develop management approaches for the improvement of highway traffic safety

(1) By effective administration of standards

(2) By coordination of various standards

4. Responsibilities in relation to administrative areas

a. Coordination of local activities

(1) Highway safety program is system made up of various sub-systems which include all the activities carried out by local agencies and organizations directly or indirectly involved in traffic safety related organizations within the community.

(2) Local government lacks administrative framework for highway safety programs.

(3) Local government lacks management tools to provide multi-functional coordination of traffic safety activities.

(a) Need to implement safety management coordination techniques

- Establish local highway safety coordinator

- Adoption of inter-agency agreements

(4) Coordination at local level

(a) Basic responsibilities of local coordinator

- Ensure that local programs conform to state and national standards

b. Organizing and administering local activities (#29)

(1) Organize subsystems into a structured framework

(a) Purpose of organization is to provide ordered structure for decision making.

(b) Human resources must be directed in unified effort toward a common goal.

(c) Productiveness will depend on character, motivation, knowledge and skill of each participant.

(d) Results will also depend on system within which individuals must work.

(e) Design of organization can inhibit or increase efficiency or effectiveness of those who operate it.

(f) Structure must permit:

- Smooth flow of ideas
- Creation of sound policy
- Efficient operation of inter-related projects

(2) Organizational problems

(a) Cohesive organizational entities at local level with responsibility for highway safety activities are virtually non-existent.

(b) Responsibility is fragmented between numerous functional agencies.

- Results in needless duplication
- Inefficient use of funds
- Gaps in highway safety services

(c) Most pressing problem in highway safety programs is lack of organization capable of effectively coordinating highway safety activities at local level.

c. Staffing local activities (#33)

(1) Highway safety activities should be administered and operated by professionals.

(2) Determine staff functions necessary to develop personnel systems tailored to special demands of each standard area.

(3) Determine manpower needs

(4) Establish recruitment procedures

(5) Provide necessary training

(6) Manpower problems

(a) Personnel policies should encompass sound staffing principles.

- A position classification plan
- An equitable payment plan
- A merit system for recruitment
- Recruit and in-service training program
- Promotion program based on merit
- A fair system of job evaluation
- A scheduled system for vacations and sick days
- An effective grievance procedure
- An effective system for maintaining discipline
- A retirement system which allows for economic security in old age

3. Worker performance and attitude

a. Union relations

b. Employee relations index

D. Measuring performance

1. Cannot measure quantitatively

2. Need qualitative standards

3. Judgment rather than data

4. Appraisal rather than measurements

V. Management Techniques

A. Management by objectives and self-control

1. It is the only management principle that

a. Establishes team work

b. Gives full reign to individual strength and responsibility

c. Gives common direction of vision and effort

d. Harmonizes goals of individuals and common weal.

2. It substitutes for control from outside the more exacting control from inside.

3. It is a philosophy of management.

a. It rests on a concept of the job of management.

b. It rests on an analysis of the specific needs of the management group and the obstacles it faces.

c. It rests on a concept of human action, human behavior and human motivation.

d. It applies to every manager, whatever his level or function and to any enterprise whether large or small.

21923

B. Proper use of reports and procedures

1. Reports and procedures can be easily misused.

   a. The belief that procedures are instruments of morality

      (1) Procedures never decide what is to be done only how it is to be done.

      (2) Right conduct cannot be established by procedure.

   b. Considering procedures substitutes for judgement.

      (1) Procedures only work where judgement no longer required.

   c. Used as instrument of control from above.

2. Reports and procedures should be kept to a minimum.

   a. Used only when save time and labor

   b. Simple as possible

3. Periodical review and evaluation of every report form

   a. Should focus only on needed performance

   b. To control everything is to control nothing

   c. To attempt to control the irrelevant misdirects

4. Reports and procedures should be the tool of the man who fills them out.

   a. Should not be used as measure of his performance

   b. Should not be judged by quality of forms

REPORTING THE COMMITTEE'S PROGRESS

Those concerned with a curriculum study look forward to reporting the findings. All of the work of the committee completed in the earlier stages must be drawn together, synthesized, and made available in a usable format.

The steps listed below suggest one pattern that might be followed in this final phase of the program:

1. Oral reporting to the committee as a whole. Individual members present their findings. These are then discussed by the whole committee, placed into their proper perspective in relation to the overall project, and summarized for the final committee report.

2. Preparation of the committee's written report. The heart of this report may be a synthesis or compilation of the individual committee findings. This part of the task will be simplified, if the study chairman has insisted on maintaining minutes of all meetings, and has required intermittent or periodic individual written progress reports to be made to him as the study or experimentation has proceeded.

One final word should be said about written reports. Be simple and be brief. Insist that written reports follow the simplest and shortest plan that serves their purpose.

3. Oral reports to total faculty by the committee. This is vital to communication. But, more important, it is necessary if the project is to conclude in a way that results in implementation of the conclusions and recommendations.

4. Oral reports to the Board of Education and to the public. There is much value in having the study committee present its work orally to the Board of Education. Such a report will inform the Board members of the outcomes and meanings of the study for the district. They can then interpret more completely to the public the significance of the project.

If desired, the committee might make its report on the occasion of a public meeting in order to gain general support for the implementation of recommendations.

Wider Distribution

Much good work is accomplished by curriculum study committees in schools. Although such work may have wide significance beyond the local school district, it fails to serve others because of a lack of distribution. Of course, school districts are not in the publishing business, but there are ways in which wider distribution can be reasonably accomplished.

For example, if a school is working with other schools on a curriculum improvement program as part of a curriculum association or council, a sharing of final written reports will prove to be a very valuable experience. New ideas are gained in the interchange; but more important is the fact that other schools may have already completed work that is being planned by a particular school. By studying such reports, they may save much time and duplication of effort.

Some schools which have special projects of great value have seen fit to reproduce and bind the work in an attractive handbook or guide and to make it available to other districts at cost. Quite often these publications can be of help to another district in its efforts.

Other examples could be given, but the important point is that curriculum findings can only receive the serious attention of others if made available for their use.

2165

- Monitor program development

(b) Suggested role of local highway safety coordinator

- Serving as an inter-agency liaison
- Liaison between commission and member governments
- Carrying decisions reached by commission
- Coordinating planning
- Plan local programs
- Develop priorities for programs
- Initiate traffic safety programs and concepts
- Directing programs
- Assist local governments in preparing applications for federal assistance
- Provide advice on request to local governments and groups
- Periodically evaluate progress of programs
- Provide staff assistance to commission
  - . Gathers and interprets data
  - . Carry out commission recommendations
  - . Needs all available information
  - . Needs time to relate federal and state program to local needs

(b) Field has acute manpower shortages.

- Need for immediate manpower expansion
- Insufficient time to mobilize resources
- Need compounded by existing short supply of qualified personnel and lack of educational opportunities.

(c) Need for increased training and education

- Lack of organized instruction
- No types of programs at state level for many types of highway safety personnel
- At local level instruction is almost non-existent.
- Instruction especially lacking at administrative and supervisory levels
- Little attention given to providing advanced education and training throughout person's career
- Existing programs are specialized within program areas.
  - . Students fail to acquire understanding of total traffic safety program.
  - . Limits on the job performance
  - . Limits lateral job entry
- Need to develop highway safety generalists

(d) Need for sufficient numbers of faculty

- Few programs to educate instructors
- Lack of standardized courses and curricula

- Scarcity of training materials and teaching aids
- Little instruction program evaluation

d. Legal authority to conduct highway safety activities (#28)

(1) Local governments derive their powers from state constitutions and state laws.

(2) Home rule charters permit more flexibility in municipal law-making.

(3) Need enabling legislation to conduct activities in some standard areas.

(4) Laws should rest on three principles

(a) Certainty -- clearness and precision

(b) Reasonableness -- relating reasonably to preservation of health and safety, moral and general welfare or public peace

(c) Uniformity -- equal protection

(5) Legal questions for local officials

(a) What state laws will affect program?

(b) What ordinances will be needed to implement program?

(c) Does local government have sufficient authority to adopt ordinances?

(d) Does local law meet test of certainty reasonableness and uniformity?

e. Financing local activities (#27)

(1) Local officials have responsibility to develop and secure financial resources needed for programs.

(8) Enact legislation requiring the recording of all blood alcohol levels of drivers, regardless of sentencing measures taken after conviction. Also refer to DMV for evaluation, any driver found to have a drinking problem.

(9) Modify court system so as to handle cases in fewer courts

(10) Establish experimental programs with probated and indeterminate sentences to deal with drinking drivers

(11) Establish uniformly among all states the .10% BAL as a standard

(12) Make provision for centralized control of chemical test methods and certification of qualified persons to conduct tests

(13) Allow for chemical testing for alcohol prior to arrest

(14) Insurance penalties

(15) Revocation of registration of vehicle

(16) Confiscation (impounding) of vehicle

(17) Medical and psychological examination as to extent of alcoholism

(18) Issuance of special license plates to identify problem drinking driver

(19) Mandatory reporting of chronic alcoholics by physicians, hospitals, etc.

(20) Mandatory BAL sampling on all hospitalized persons as a result of a traffic crash.

2. Staffing for alcohol and highway safety

a. Personnel trained in operation of intoxication measuring devices

b. Personnel trained to supervise and/or inspect devices

c. Lab technicians and/or analysts

d. Rehabilitation personnel

(1) Psychiatric social workers

(2) Psychologists

(3) Social psychologists

(4) Administrators of rehabilitation programs

(5) Nurses

(6) Medical doctors

(7) Group therapists

(8) Social workers

(9) Counselors

F. Pedestrian Safety

1. Legal implications

a. Standard provides for

(1) Inventory of pedestrian-vehicle accidents

(2) Improved protection of pedestrians

(3) Improved education programs to acquaint drivers with pedestrian problems

(4) Improved education programs of traffic rules for pedestrians

b. Nature of pedestrian regulation

(1) Insure efficient and safe movement of people

(2) Relate to two essential problems

(2) Can add safety function to other federal and state aid support programs

(3) Local officials should be aware of sources of financial assistance available from federal, state and private sector. (See source document of NACO, Vol. IX of their series.)

f. Public support for local activities (#31)

(1) Safety activities must have public support and involvement to be effective.

(2) Local officials should develop public information programs directed to increase public concern and response.

(3) Local officials should create methods to increase public awareness of highway safety activities and use all sources to solicit support.

VIII. Legal Implications and Staffing Considerations for Management of Selected Standard Areas (#33)

A. Codes and laws

1. Legal implications

a. Standard requires each state to have plan to achieve uniform rules of the road.

b. Local governments should adopt model ordinance.

c. Tools for planning in legal area

(1) UVC (Uniform Vehicle Code)

(2) MTO (Model Traffic Ordinance)

2. Staffing for codes and laws

a. Need program specialist at state level

(1) Undertake continuous review of state and local laws, statutes and ordinances

(2) Ensure conformance of above with national standards

b. Local official should be designated to establish liaison with state program specialist.

B. Traffic courts

1. Legal implications

a. Theoretically every person charged with moving violation should go to court.

b. Courts do not have adequate judicial, administrative, and clerical personnel.

c. Those committing non-hazardous violations are permitted to admit guilt and pay fine without going to court.

d. Standard attempts to encourage uniform procedure in handling cases that go to court.

e. Local traffic courts must have jurisdiction

f. Functional aspects of traffic court standards

(1) Hearing of cases

(a) Jurisdiction to hear traffic cases exists in all states.

(2) Reporting convictions

(a) Courts required by law to report convictions of motor vehicle violations to state licensing agency.

- Records essential for administration of driver license programs.

- Provide bases for courts to analyze own performance

(5) Should have qualities of character that demonstrate broad personal excellence

(6) Appointment of judge should be free from community pressures.

(7) Judge should ensure that traffic court program becomes integral coordinated part of total community highway safety program.

(8) Judge should establish liaison with other pertinent agencies.

b. Other traffic court staffing roles

(1) Court administrator

(2) Clerk of the court

(3) Court officer

(4) Court liaison officer

(5) Court recorder

(6) Prosecutor

(7) Defense counsel (public defender)

(8) Traffic referees

(9) Juvenile referees

(10) Probation officer

C. Emergency medical services

1. Legal implications

a. Many people die each year due to inadequate care

(1) At scene

(2) Enroute to hospital

(3) Emergency reception room at hospital

b. Ambulance attendents lack sufficient training

c. Inadequate legislation to assure level of competency to be consistent with responsibilities of ambulance attendent

d. Inadequate equipment

e. Laws regulating ambulance service are vague and inadequate.

f. Reasons for ambivalence and the ambiguity of EMS law

(1) Morticians provide over 50% of service

(2) State legislators reluctant to pass stringent standards which might effect marginal operations.

(3) Local officials and legislators are unwilling to exceed state requirements. They have no legal frame of reference based on local experience.

(4) Systems with financial capability to exceed state standards are under no legal obligation to do so. Thus, regulation is conditioned by lowest levels of performance, rather than serving as a model of excellence.

g. Most existing ambulance statutes and ordinances are fragmented.

(1) Authority is delegated to several agencies with no clear indication of responsibility of each.

(2) Model legislation needed to correct these inadequacies.

h. Need for legal flexibility to allow an attendant with sufficient training to perform basic life-saving procedures now permitted only nurses or physicians

i. EMS standard requires for each state in cooperation with its political subdivisions:

(1) Training, licensing, and related requirements for ambulance and rescue vehicle operators

(2) Requirements for types and number or emergency vehicles including supplies and equipment to be carried

(3) Requirements for operation and coordination of ambulances and other emergency care systems

2. Staffing for emergency medical service

a. Ambulance service personnel

(1) Administrative supervisor

(2) Training supervisor

(3) Operation supervisor

(4) Shift supervisor

(5) Attendant

(6) Driver

(7) Communications technician

(8) Dispatcher

(9) Mechanic

b. Para-medic personnel

D. Driver education

1. Legal implications

a. Legal authority to conduct driver education in schools has long been established.

b. Legislative support provided for driver education in several ways.

(1) Special instruction permits for students of approved courses

(2) Many states require applicants under 18 years of age to have completed driver education. Also in the Uniform Vehicle Code.

c. States regulate control of high school driver education as well as preparation of teachers.

(1) Teachers must possess a valid operator's license.

(2) Teachers must have a driving record free from repeated accident and violations.

(3) Teachers are required to have a given educational level, varies among states.

d. Driver education legislation is concerned with

(1) Age limits of driver applicants for driver education course

(2) Establishing medical advisory boards for driver licensing

(3) Funding of driver education programs

(4) Provision of driver education in the schools

(5) Regulation of driver education schools and/or instructors

2. Staffing driver education programs

a. Driver education teachers

(1) Need for increase in number of teachers in commercial and secondary schools

(2) Need for additional instructors for behind-the-wheel phase of driver instruction

(3) Need to initiate development of effective recruitment program

(4) Success of educational programs depends on quality leadership provided by colleges and universities.

(a) Setting of high entrance requirements

(b) Raise quality of instruction

(c) Expand range of course offerings

b. Driver education supervisors for school systems

(1) Manage staff of driver education teachers

(2) Insure that students receive uniform comprehensive instruction

(3) Performs coordination service

(4) Background should reflect substantial course work in driver and traffic safety education.

(5) Should have teaching experience

c. Area-wide driver education center coordinators

(1) Should have experience in supervising or coordinating driver education programs

(2) Should have specialized and general knowledge in field

(3) Should hold advanced degree in safety education, educational administration, or supervision

E. Alcohol and highway safety

1. Legal implications

a. Most states have laws prohibiting a person from operating a vehicle after he has consumed alcohol to such an extent that his driving ability has been impaired.

(1) Some have not included "physical control" aspect.

(2) Many have combined references to drugs with those relating to alcohol.

b. Conviction for DUIL or DWI is usually followed by some action against defendant's license.

(1) Some states' license action is permissive

(2) Others require mandatory revocation or suspension

c. Catagories of laws under which alcohol highway safety programs are enforced

(1) Impaired driving laws

(a) Prima facie evidence of .15% or more of alcohol by weight

(b) Prima facie evidence of .10% or more of alcohol

(c) Prima facie evidence of .05% BA level for anyone under 21 years of age

(2) Implied consent laws

(a) Exist in most states

(b) Differ among the states

(3) Laws involving chemical tests

(a) Tests are used to determine percent by weight of alcohol in an individual

FORMAT FOR PROGRESS REPORT

The outline on this page is intended to serve as a guide for the preparation of a curriculum study committee's annual or periodic progress report. The basic report, including the ideas listed in Parts I through IV below, might run from two to ten mimeographed pages. The appendix might be as long or longer.

Sufficient copies of the report should be run off for the superintendent's office, board of education, all administrators and faculty members, the curriculum council or association to which the school district may belong--plus a supply for new teachers the following year. The responsibility for the preparation of this report should be that of the committee chairman--with the help of the consultant.

The Cover Page

This should be an attractively-spaced page perhaps in color, including the following information:

Name and address of school district
Title of project
Name of superintendent
Names of committee members and chairman
Name of consultant
Mention of affiliation with area study council
Date (month and year)

The Basic Report

Part I Brief description of the overall project, including its purpose, its scope, its goals.

Part II Descriptions, perhaps of one paragraph each, of sub-projects or individual studies or experiments, including purpose, results to date, subject or grade level, teacher's name.

Part III General conclusions on the part of the committee, even if only tentative.

Part IV Specific recommendations to the superintendent of schools including (1) curriculum proposals, policy revisions, or purchases of equipment, supplies, or materials for the following year, and (2) proposals for continuation, completion, or implementation of the committee's study.

Appendix

The appendix to the report might include some of the best examples of work produced by the committee, such as:

Informal tests, exercises, or outlines developed by teachers
A full page description of the most significant experiment tried
Annotated bibliographies of materials on a specific topic
Reviews of important teaching materials which have been tried
Lists of Do's and Don'ts for teachers
Recommended outlines of concepts to be taught at various levels of schooling
Outline or handbook developed by the committee

2166

(3) Education

(a) Courts have role in re-education of drivers

(b) Authority to sentence drivers to driver improvement school

(4) Presentence investigations to probation

2. Staffing traffic court programs

a. Traffic court judge

(1) Respect for court depends upon presiding judge.

(2) Judge should wear judicial robe.

(3) Judge should have knowledge of:

(a) Traffic laws

(b) Traffic engineering and policing

(c) Traffic problem and its relationship to his work

(4) Should have a legal background

(a) Familiar with trial procedure

(b) Familiar with presentation of evidence

(c) Knows constitutional law

(d) Knows statutory law and regulations

(e) Knows essentials of court administration

(f) Must establish administrative policy

(g) Has responsibility for overall supervision of court

(b) Evidence obtained is admissible in court of law.

(c) Evidence is rebuttable.

(d) Nature of tests:

- Blood
- Saliva
- Urine
- Breath
- Tissue

d. Proposed changes for dealing with problem

(1) Regulate post-mortum investigations

(2) Mandatory revocation of operator's license upon conviction of DUIL

(3) Authorize discretionary administrative action in suspending operator's license when evidence that driver has committed an offense serious enough for revocation upon conviction.

(4) Establish immunity from lawsuits for physicians and others who draw blood specimens.

(5) Require that analysis of alcohol specimens be conducted by procedure which is considered specific for ethyl alcohol.

(6) Make jail or treatment mandatory for those found guilty of DUIL.

(7) Require all convictions of DUIL to be recorded, regardless of sentence.

(a) Time

(b) Space

(3) Protect pedestrian's rights

(a) Control unreasonable usurpation or extension of these rights

(b) Jaywalkers are seldom prosecuted.

(4) Model traffic ordinance regulations

(a) Crossing only at right angles

(b) Prohibiting crossing in business district outside of crosswalks

2. Staffing for pedestrian safety

a. Police safety officer

b. Adult school crossing guard supervisor

c. School crossing guard

d. School route map analyst

e. Public relations personnel

f. Others who contribute

(1) Traffic engineer

(2) Accident records analyst

(3) Driver education instructor

(4) School officials

G. Highway design, construction and maintenance

1. Legal implications

a. Purpose of standard is to assure streets and highways are:

(1) Maintained in safe condition

(2) That new improvements meet standards.

(3) That approprite precautions are taken to protect motorists and highway workers at construction sites.

b. Main issue of function of maintenance and construction is who has authority to do the work

(1) All roadways should be under control of some jurisdiction.

(a) State legislation usually has made broad classification of road systems.

- State highways
- County roads
- City streets

(b) Problem with this classification

- Lesser jurisdictions are included in larger ones which often result in overlap.
- Roads cross jurisdictional boundaries.
- Certain road systems need individualized legislative action.

2. Staffing for highway design, construction and maintenance programs

a. Staff requirements for this standard range from professional engineers to road maintenance crews.

b. Position classifications

(24) Maintenance craftsman

(25) Mechanical maintenance foreman

(26) Mechanic

(27) Mechanical serviceman

(28) Administrative assistant

(29) Programmer

(30) EDP Operator

(31) Clerical positions

H. Traffic control devices

1. Legal implications

a. Traffic control devices include signs, signals, markings, and lines placed to regulate, warn, and guide traffic.

b. Uniformity of devices necessary.

c. Clarity is very important. Driver must know at a glance what a device means.

d. Purpose of standard

(1) Assure that devices conform to specifications of Federal Highway Administration.

(2) Promote use and application of efficient traffic engineering practices

(3) Promote installation of uniform devices

(4) Calls for identification of deficiencies of existing devices

(5) Calls for preventive maintenance and efficient repair practices

e. Most states authorize local communities to place and maintain traffic control devices.

(3) Police Traffic Services Deputy Administrator of Field Operations

(4) Director of Police Traffic Training

(5) Director of Communications

(6) Director of Research and Development

(7) Police Traffic Services Supervisor

(8) Accident Investigation Supervisor

(9) Vehicle Inspection Supervisor

(10) Breath Examiner Specialist Supervisor

(11) Supervisor of Training

(12) Public Information Officer

(13) Supervisor of Fleet Management

(14) Communications Engineer

(15) Police Traffic Services Patrolman

(16) Traffic Accident Investigation Specialist

(17) Police Traffic Control Specialist

(18) Motor Vehicle Inspection Specialist

(19) School Bus Inspection Specialist

(20) Policewoman (metermaid)

(21) Police Traffic Services Training Instructor

(22) School Resource Officer

(23) Communications Officer

(24) Dispatcher

K. Traffic records and identification and surveillance of accident locations

1. Legal implications

a. Traffic records standard calls for coordinated

(1) Collection of data

(2) Storage of data

(3) Retrieval of information

b. Types of information are:

(1) Information on drivers, including licensing violations and financial responsibility

(2) Information on vehicles, including make, model, and seriel number

(3) Information on highways, i.e. structures, traffic control devices, curves, intersections

(4) Information on accidents, such as drivers involved, vehicles, locations and road conditions

c. Barriers to record system

(1) Non-uniform accident reporting

(2) Inadequate reports submitted to state

(3) Data is frequently never analyzed and used to update programs.

(4) Limited public cooperation in accident reporting

d. Most local governments have established some form of identification and surveillance systems.

21957

e. Needed legislation in traffic records and identification and surveillance standard areas

(1) Require all police to submit written reports on every motor vehicle accident investigated to Department of Motor Vehicles on form provided by DMV.

(2) Prescribe that minimum information on accident report form should enable:

(a) Measurement of magnitude of accident problem

(b) Definition of major traffic problem areas

(c) Selection of modes of prevention action

(d) Measurement of countermeasure effectiveness

(e) Judgment if additional research is needed for effective programs

(3) Require gathering of information about high accident locations so as to develop improvement programs

f. Legislation should require

(1) Uniform, complete, and accurate accident reports

(2) Stored in one center in every state

(3) Subject to rapid retrieval and analysis

(4) Compatible with national record system

(1) Chief engineer

(2) Deputy engineer

(3) Special project engineer

(4) Traffic engineer

(5) Engineering aid

(6) Design supervisor

(7) Design engineer

(8) Surveyor

(9) Instrument man

(10) Survey helper

(11) Right of way supervisor

(12) Right of way agent

(13) Construction supervisor

(14) Construction inspector

(15) Construction engineer

(16) Construction foreman

(17) Construction craftsman

(18) Heavy equipment operator

(19) Light equipment operator

(20) Bridge operator

(21) Maintenance supervisor

(22) Materials inspector

(23) Maintenance foreman

(1) Care must be taken to make sure this is done only on roads within local jurisdiction

(2) Devices must conform to state standards.

(3) Ordinances must be reasonable

f. Most states have either adopted manual of uniform traffic control devices or have state laws conforming to the provisions of the manual.

g. Traffic control devices should conform to requirements.

(1) Any device should be capable of fulfilling desired need.

(2) Any device should command attention.

(3) Any device should convey clear simple meaning.

(4) Any device should command respect of road users.

(5) Any device should be located to give adequate time for response.

h. Elements to assure fulfillment of above requirements

(1) Design

(2) Placement

(3) Operation

(4) Maintenance and uniformity

2. Staffing for traffic control devices

a. Traffic engineer

(1) Major functions

(a) Planning

PUTTING IDEAS INTO ACTION

The results of a study will be meaningful only if they have a real effect on the existing curriculum. The only way to assure that this occurs is to follow-up the study with action on the recommendations.

The file cabinets and desk drawers across the country are full of curriculum studies that have been made. In each case recommendations have usually been made to the authorities. But, too often, the studies end at that point because of a lack of follow-through.

This may occur (1) because the committee is dissolved by the administration as having completed its work, (2) because committee members are weary after their long labors, (3) because the administration having the responsibility for following up the study neglects to do so as the result of new and different pressures, or (4) because the implementation of the recommendations was not clearly understood in advance.

Whatever the reason, the result may be the same--the failure to culminate the study with meaningful and immediate action. Nothing can be more disastrous to the morale of those involved. The damage to the long-range prospects of future curriculum study efforts is devastating.

Necessary action should be taken, therefore, as soon as possible on the recommendations, to take advantage of the interest of the staff while it is at a peak.

HAVE WE DONE WHAT WE COULD?

Here are two checklists for putting committee proposals into action:

What the Committee Asks Itself

_____Have our recommendations been clear and specific?

_____Have we suggested a step-by-step implementation?

_____Have we suggested probable costs for each recommendation?

_____Can our recommendations be supported by our evaluations?

_____Are recommendations that require additional costs timed to the development of the school budget?

What the School Superintendent Asks Himself

_____Have I read the recommendations carefully?

_____Have I discussed them with the Committee or its chairman?

_____Have I discussed the recommendations with the board?

_____Have I carefully reviewed the board's reactions with the chairman?

_____Have I explained to the staff the plans for action on recommendations?

_____Have I incorporated the approved plans in the budget requests?

_____Have I discussed the recommendations with other official leaders?

2167

(b) Design

(c) Construction

(d) Operations

b. Assistant to traffic engineer

(1) Often is engineer from another speciality

(2) Technicians

(3) Student help

c. Position classifications

(1) Field investigator technician

(2) Traffic records analyst

(3) Traffic engineer

(4) Traffic engineer specialist

(5) Traffic control device technician

(6) Traffic control device craftsman

(7) Traffic control device laborer

(8) Clerical positions

I. Debris hazard control and clean-up

1. Legal implications

a. Effective implementation of standard requires close coordination and cooperation of number of functional departments of local government.

(1) Ambulance companies

(2) Tow truck operators

(3) Local and state police

(4) Health departments

(5) Other

b. Must plan for a variety of contingencies and establish policies and procedures which outline legal responsibilities of local departments.

c. Standard requires that drivers be warned of hazards and rerouted if possible.

(1) Use of traffic control devices

(2) Use of police to detour motorists

d. Transportation of hazard materials is controlled by state legislation.

(1) Requires local enforcement

(2) Should cover various aspects

(a) Hazardous cargo identification

(b) Special handling precautions

(c) Emergency procedures

(d) Transportation of hazardous materials regulated by DOT

(1) Developed on a case by case basis

(2) Consists of a collection of miscellaneous rules and procedures

2. Staffing for debris hazard control and clean-up

a. Activity involves several functional departments as well as resources from private sector.

b. Central manager of accident clean-up

c. Emergency patrol driver

d. Dispatcher

J. Police traffic services

1. Legal implications

a. Enforcement agencies from all governmental jurisdictions (state, county, city) possess a wide range of functions and authority including:

(1) Accident prevention

(2) Enforcement of rules

(3) Accident investigation

(4) Emergency medical aid

(5) Others

b. Much overlap in jurisdictions

c. Nature of state police agencies

(1) Sixteen states have state police forces.

(2) Nine states have highway patrols.

(3) Nine states have DPS which functions as state police.

(4) Seven states have DPS which functions as highway patrol.

(5) Eight states which have a highway patrol that is part of another governmental unit.

(6) Hawaii has no state police agency

d. Nature of traffic enforcement in local police agencies

(1) Sheriff's traditional responsibility as chief law enforcement officer of county

(2) Delegation of sheriff's traffic enforcement responsibility to highway patrol and municipal departments

(3) Contract or agreement by sheriff to provide traffic law enforcement for small communities

(4) Cooperative efforts between various agencies

e. Police agencies in all the states leave traffic services on city streets to city police department.

2. Staffing for police traffic services

a. Police are principle sources for

(1) Control

(2) Inspection

(3) Investigation

(4) Reporting of community condition

b. Recruitment

(1) Attracting competent manpower requires desirable jobs.

(2) Quality working conditions stimulates high morale and performance.

(3) Salaries should not depend on fines or court penalty assessments.

c. Police traffic service positions

(1) Police Traffic Services Administrator

(2) Police Traffic Services Deputy Administrator of Administrative Services

2. Staffing for traffic records and the identification and surveillance of accident location programs

   a. Accident investigator and aids

      (1) Has burden of establishing high quality accident data

      (2) Requires high level of training

   b. Highway and traffic engineering personnel

      (1) Must be familiar with high accident locations

         (a) Conduct continual surveillance

         (b) Specify what conditions should be

      (2) Must recognize conditions that contributes to accident

      (3) Must repair hazardous condition

   c. Traffic records analyst

      (1) Essential to determine causes and corrective measures

      (2) Will need support personnel

         (a) Programmers

         (b) Computer operators

         (c) Records clerk

         (d) Office machine operator

PART V

PROGRAM IMPROVEMENT

I. Methods and Principles of Program Improvement

A. Nature of Research and Development

1. Categorization of Activities

a. Broad ambiguous division of research

(1) Basic

(2) Applied

b. Traditional taxonomy for research

(1) Historical research

(2) Experimental research

(3) Surveys and studies

(4) Ex post facto (cause/effect) studies

c. New paradigms of research and development (little or no previously established procedure)

(1) Developmental projects

(2) Theory development projects

(3) Projects integrating knowledge

(4) Services projects

(5) Research integration studies

(6) Performance prediction studies

B. Conducting Task Analysis

1. Methods of conducting task analyses and job

descriptions for organizational positions

2. Quantitative Perspectives for selecting Managers

   a. Must have history of striving for personal betterment and a high level of energy/drive/motivation for application to the problems he faces.

   b. Must have a rich fund of experience. Must have seen life and business from a variety of perspectives.

3. Analysis of task of Highway Safety Management

   a. Understands the traffic problem

   b. Understands administrative function

   c. Knows organizational structure

   d. Understands function and use of records

   e. Knows purpose and function of data processing

   f. Identifies and analyzes needs

   g. Collects data for decision-making

   h. Compares alternatives

   i. Develops policies and directives

   j. Plans and directs program execution

   k. Checks performance against established standards

   l. Evaluates performance

   m. Directs planning and research

   n. Maintains control as management function

   o. Manages personnel

p. Manages business affairs

q. Prepares budget

r. Cooperates with other agencies

s. Participates in community affairs

t. Obtains public support

u. Directs preparation of materials

4. Tasks in Local Highway Safety Management

a. Role of Local Highway Safety Coordinator

(1) Should be a generalist in the field

(2) Should understand full significance of highway safety program standards

(3) Should possess capability to implement standards

(a) able to achieve coordination of services provided by local, regional, state, and federal government agencies as well as private interests concerned with highway safety activities

(b) important point of contact between community and government representatives

(4) Should acquire thorough knowledge of traffic problems in community

(5) Should understand the relationship of these problems in the administrative function of traffic related agencies

b. Suggested duties of local coordinator

(1) Maintain liaison with government representatives through monthly meetings and written communication

(2) Keep records of projects and grant applications

(3) Insure that project directors are keeping records

(4) Determine local funding capability

(5) Establish a local highway safety advisory committee

(6) Take an active interest in:

(a) traffic engineering improvements

(b) public school safety education programs

(c) public support through stimulation of business and industry

C. Use of Case Study Method to Develop Understanding and Insight into Management Problems

1. Development of Case Study

a. Definition

b. Scope of a Case Report

c. Organization of a Case Report

(1) Problem

(2) Relevant facts

(3) Alternative decisions

(4) Making the decision

(5) Decision implementation

(6) Evaluation

2. Case of the 2:00-4:00 a.m. Parking Control Directive (See Appendix for complete case)

a. Sets Forth Poor Policy Development and Improper Implementation

b. Portrays Several Generalizations regarding Principles of Management

(1) Initiation of any administrative policy decision will result in similar resistance to change and create like problems in the initial stages of development

(2) The administrator making most of the decisions stymies initiative and instills distrust in subordinates

(3) For an administrator to give an adequate amount of thought-time to long range problems, he must delegate many decisions

(4) Internal acceptance of policy making decisions is necessary before external application can successfully take place

(5) Malum prohibition laws require public support before appreciable enforcement can take place

(6) Better decisions occur when they are made with the aid of a staff or persons concerned with the issues

(7) The administrator must consider departmental policy, and the law and its precedence, special interest

CHAPTER VII

The CDC in Operation

The dream came out of a conference of public school administrators and professors of education at Glassboro State College, a teacher preparation institution. The idea was to establish a regional study council which, through in-service work with teachers, would substantially affect curriculum and instruction in the public schools.

The first step was taken by the college. A preparatory committee of interested professors, headed by a former public school administrator who was to serve as executive secretary of the new organization, began to formulate ground rules. A sample of public school superintendents, principals, and curriculum supervisors was polled on their views and hopes.

The committee drew up a prospectus which proposed three major functions for the organization, to be known as the Curriculum Development Council for Southern New Jersey:

> To develop, coordinate, and publish selected curriculum studies in which member schools participate, and from which they can profit educationally.
>
> To share ideas through Council meetings and workshops, a regular newsletter, and at least two published study reports per year.
>
> To effect close, systematic communication and working relationships between the college and member schools.

2168

groups and factors affecting internal and external support in creating decisions

(8) Information concerning the "pulse of the community" is most difficult to obtain, therefore the administrator must have experience in predicting the reaction of the community to a given type of decision

(9) Any administrative decision that requires departure from established behavior must be programmed into acceptance by those affected

(10) Unless adequate explanation appears, operation policy decisions can be enforced and interpreted in as many ways as there are persons responsible for its implementation

D. Role of Colleges and Universities (#21)

1. Education institutions have not established instruction programs for highway safety personnel other than for driver education teachers and traffic engineers

2. University traffic safety centers can perform several functions to assist in augmenting the force of highway safety manpower

a. Education and training of a wide variety of highway safety personnel including researchers, administrators and supervisors, professional specialists and technical personnel, instructors, directors and coordinators of educational programs

b. Research and development activity that ranges from basic research to simple surveys, including applied research, experimentation and developmental projects. Incorporating research findings into ongoing activity of various agencies.

c. Service activity which encompasses a wide range of types of assistance to agencies responsible for implementation of the standards. These services could be:

(1) Implementing research into action

(2) Providing technical information

(3) Evaluating program performance

(4) Analyzing problems and programs

(5) Assessing improvement needed

(6) Program and project planning

(7) Developing manuals and procedural guides

(8) Surveying particular activities

(9) Planning and execution of experiments

(10) Assisting legislative committees

(11) Stimulating professional activity

(12) Provide consultation

(13) Provide expert opinion on issues and needs.

3. Educational institutions should provide degree programs as well as non-degree programs.

E. Role of local government agencies

1. Should structure training and education programs to meet local needs.

2. Operational staffs should be instructed in interrelationships of the standard areas.

3. Cooperative programs should be developed with universities and centers.

a. Pool resources into management institutes

b. Could provide entry education to various public service careers

c. Could provide in-service training for middle management and supervisory positions

F. Areawide management approaches (#26)

1. Definition and principles of areawide request

a. Defined as either a formal or informal agreement or cooperative arrangement between or among two or more local jurisdictions for purpose of achieving mutually agreed upon goals.

b. Activities should be coordinated in accordance with geographic areas large enough to accomplish effectiveness and economy.

c. Some standard areas are best operated by one government.

d. Some standard areas lend themselves to multi-jurisdictional management.

2. Problem of fragmented jurisdictional management

a. Preponderence of local government units independently arranging traffic safety programs.

(1) overlap geographically, functionally, and representationally.

(2) 81,000 independent units.

(a) 3,000 counties

(b) 35,000 cities and villages

(c) 22,000 school districts

(d) 21,000 special districts

b. Preponderence of social mobility

c. Disparity and lack of uniformity in programs. services and laws between jurisdictions.

(1) creates sharp inequities in service

(2) creates confusion

(3) creates non-compliance and general disrespect for the law

d. Need system to promote concept of highway safety as a comprehensive effort designed to reduce accidents

(1) need mechanism of coordination

(2) need mechanism of cooperation

(3) need management approaches which prevent

(a) fragmented nature of existing activities

(b) duplication of effort

(c) wasted resources

3. Rational for area wide approach for problem solving.

a. Recognizes the fact that some problems cannot be solved by single local government entity acting alone.

b. Problems affecting local governments do not respect political or administrative boundaries.

c. Local governments are challenged to provide new services that traditionally have been beyond this responsibility.

(b) Operationally this involves

- collecting basic data from area as a unit.

- synthesizing these data to portray jurisdictional interrelationships.

c. Advantages of areawide approach

(1) Elimination of duplicated effort

(2) Uniform procedures and programs

(3) Greater flexibility in program administration

(4) Economics of scale

(5) More effective method of obtaining federal and state financial and technical assistance

5. Criteria for areawide organization

a. Conditions which necessitate areawide coordination.

(1) Nature of person currently responsible for a particular activity

(2) Nature of jurisdiction currently doing work (large enough, too large)

(3) Nature of jurisdictions resources to do work effectively and efficiently

b. Criteria to be considered.

(1) Prerequisite is state enabling legislation

(2) Need for adequate funding

(3) Function to be administered must be

e. Necessary to develop effective management and coordination procedures to conduct multi-jurisdictional activities.

f. Proper professional management may not be cost/effective for small local communities.

4. Concepts involved in an Areawide Approach

a. Historical development

(1) Federal role

(2) Action at state level

b. Functions of areawide organizations

(1) Agreements and contracts are the usual mechanisms to create areawide organizations.

(a) Usually exist as advisory bodies

(b) No authority to implement plans

(c) Authority for implementation reserved within decision-making power of individual member jurisdiction.

(2) Primary function to coordinate activities and programs between jurisdictions.

(a) coordination responsibility takes form of planning how function of several jurisdictions might be discharged.

(b) contributes to economical and efficient delivery of services.

(3) Major function is to develop and demonstrate practicalities of centralized management.

(a) Purpose is to promote conditions

311 OF 327
ED
056 238

(d) Functions based on fixed rate, variable rate, and efficiency.

(e) Alternative ways to take advantage of economies of scale.

(f) Ways to make equitable to private vendors efficient

(g) Ways to encourage in public.

(h) Encouraging of Expansion of other

(i) Reference Materials.

(j) Alternative ways to provide equitable and economically feasible School Services and facilities

3. Supplementary services and facilities

a. Consolidation of individual units.

(a) Establishing regional administrative units

(b) Establish multi-functional units

(c) Use of Intermediate units

(d) Ways to make regional activities or programs.

(e) Model methods of contracting services

(f) Alternative methods for contracting services provided on contract basis

(g) Alternative methods

(h) Issues of county-city management

(i) Transfer of function

(j) Jurisdiction extreme service

b. Charter of Governance

(1) Alternative approach to other forms of governance and control

(a) Non-existent or functional case

(b) Not subject to principles for contracting services

(c) Alternative ways for creating centers of Governance

c. Alternatives for intergovernmental cooperation.

(d) Model methods for contracting services

(e) Alternative methods for contracting services provided on contract basis

(f) Alternative methods

(g) Issues of county-city management

(h) Transfer of function

(i) Jurisdiction extreme service

b. Charter of Governance

(1) Alternative approach to other forms of governance and control

to the average citizen who is not concerned about thefts or noise, unless it directly affects him. Captain Bright did not consider the full legal aspects of such a law; departmental policy toward the enforcement; ethical questions; special interest groups; political factors; internal station morale; and external or public relations considerations before the decision was made. It was evident that he considered these factors only after someone of higher authority or a special interest group complained about a problem created by enforcing or not enforcing the ordinance. In other words, the Captain did not establish valid criteria in which to judge community complaints.

Many police decisions affect the public and should be widely announced and clearly explained prior to enforcement. Captain Bright should have developed some universal method of announcing and explaining the necessity for enforcing the 2:00 am to 4:00 am parking law.

Once enforcement took place, complaints for such enforcement flooded the station. Here again, a law enforcement officer must enforce statutory laws, especially when a formal complaint is made. The Captain did what was legally required, however, personnel enforced the ordinance without using discretion. Whether it was in retaliation to unfavorable personnel policies initiated by the Captain or a method to

embarrass him is for the reader to decide. The men apparently realized the Captain had created a paradox. They could enforce any law in the legal manner as they desired. Their strict enforcement of the parking law resulted in the Department reassigning the Captain to a position where his decisions could not directly affect the community.

Generalization

Many of the generalizations contained in this case study have been listed in the evaluation of the case. To ensure that the learning process of the case study is complete, those generalizations and others that apply to the study are enumerated.

1. Initiation of any administrative policy decision will result in similar resistance to change and create like problems in the initial stages of development.
2. The administrator making most of the decisions stymies initiative and instills distrust in subordinates.
3. For an administrator to be able to give an adequate amount of thought-time to long range problems, he must delegate many decisions.

SOME EARLY DECISIONS

A decision was made to form a non-profit educational corporation with annual dues, ranging from $300 to $800 depending upon pupil enrollment, for each member public school district. The college agreed to underwrite meeting space, secretarial service, and salary for the executive secretary.

Control of the Council would be vested in a Board of Trustees to include three superintendents of member school districts elected by their peers; three staff members of the college appointed by the president; and one county superintendent of schools chosen by his colleagues in southern New Jersey.

The Council would be similar to other school study councils in that it would offer its members publications on educational research and experimentation, and its members would share ideas and promote curriculum development at a reduced cost.

The new organization would differ from most Councils, however, by limiting its research to curriculum matters of interest to schools in the local geographical area, and by involving consultants for its scheduled studies to work directly with staff members in the member schools.

It was decided to proceed with the plan if a minimum of 20 school districts joined--enough to make the organization financially feasible. After an informative campaign through mailings, talks at county-wide educational roundtables, publicity at the state education association convention, and personal contacts, 42 districts signed up in the spring of 1963 for the following school year. The unanticipated number indicated a fine degree of interest in the plan, but was later to prove something of a strain on the resources of the new organization.

THE FIRST YEAR OF OPERATION

For the school year 1963-64, the planning group limited Council activities to two major study areas. Fourteen districts chose "Reading in the Secondary School" as their year's project, while 28 other districts chose "Study Skills and Critical Thinking."

Ten consultants, members of the college staff, chosen for their technical competence and ability to work with public schools, visited the districts an average of eight times each during the school year, met with local committees, and aided in planning or revising programs designed to meet the needs of each particular school system.

The Board of Trustees met regularly to establish policies and precedents for the fledgling organization. A College Resource Board, including representatives from every department at the college, served the Council in an advisory capacity.

During the year the new Council conducted several conferences:

An all-day conference for orientation of all local committee members in October.

Meeting of consultants with leaders from the state department of education on policy coordination in December.

Leadership conference for all local study chairmen in January.

An exchange-of-ideas conference for all local committees in February.

The annual meeting and superintendents' evaluation forum in April.

A leadership conference for the following year's chairmen in May.

one, including his fellow officers. He never married, lived alone and enjoyed good food and fiction novels.

Grandview Patrol Station is one of ten stations located within the city that provides services for over 1 million people. It covers 40 square miles and has a mixture of single and multiple dwellings with business establishments located on the main streets.

Captain William Long commanded the station for 4 years prior to Captain Bright's assignment. Morale was good, the men were able to pick their work shifts according to seniority. The crime rate was the fourth highest in the city for all major offenses. In general, the patrolmen considered Captain Long as a good able administrator, easy to get along with and democratic in his dealings with the men.

New Policies

During the first two months under Captain Bright's administration, the station and its policies remained the same. In March, 1967, the first new administrative decision appeared on the bulletin board announcing that all patrolmen of Grandview Station would conform to department rules and regulations by not accepting free meals. Up to this time it had been the practice by patrolmen to accept free meals. Effective one week later, a station order was posted

to notify members of the patrol force that beginning April 1, 1967, all patrol and traffic officers would be assigned to different cars on rotating shifts. The immediate reaction to these new orders was resentment toward the new Captain. Many veteran officers, who had been assigned to the station for years had outside or extra jobs and planned their shifts to meet the extra employment. Twenty-two men requested a transfer to other patrol stations in the city that still ran their duty assignments according to seniority. Morale began to deteriorate.

In early April, 1967, Mr. Sirmans, representing home owners in a mixed neighborhood of apartments and single residences wrote a letter to the Captain complaining about the streets being cluttered with cars, some considered junkers, numerous thefts in the area and people sitting in cars during the early morning hours making loud noise.

The Captain conferred with his Lieutenants and Sergeants about the complaint and advised them a directive would be submitted regarding enforcement of certain laws to handle the situation. Sergeant Smith asked Captain Bright what law did he have in mind? The Captain stated he was thinking of enforcing the no parking ordinance between 2:00 am to 4:00 am daily. No other opinions or questions were asked by the staff or other information offered by the Captain.

THE LEADERSHIP CONFERENCE

Perhaps the most significant meeting of the year was the first Leadership Conference, attended by local district committee chairmen and conducted by college staff members.

In this all-day session real problems of the local chairmen were taken up. These, of course, could have been predicted from a reading of the literature referred to in Chapter II of this Handbook, but had not been seriously examined up to this point.

The minutes of the meeting were published as a mimeographed document called "What Kind of Leadership?" which was the predecessor of this Handbook.

District committees developed an annual report, mimeographed for distribution to all member districts as well as for home consumption. Reports contained conclusions and recommendations directed specifically at the local district administration.

From these reports and from a wealth of personal experience, the consultants wrote two Handbooks which were published for member districts and general public sale: Reading in Grades 7-12 and Teaching Study Skills.

At the end of the first year, 31 districts renewed their contracts with the Council, and five new districts joined. Districts which dropped out of the Council did so for a wide range of reasons: lack of finances due to budgetary problems, school staff and consultant not knowing how to function effectively together, choice of a study topic which the staff felt was not important, a feeling that the district could now continue its curriculum work without the aid of the Council.

THE SECOND YEAR

For the second year several changes were made in the operation of the Council. The Trustees enlarged the choice of study areas for member districts to include any project in curriculum for which the Council could find adequate consultant service.

A number of systems continued their initial studies. Other choices included:

- Reading at the elementary level
- A program for the culturally different
- Classroom dynamics
- The reluctant learner
- English K-12
- Social Studies K-6
- Modern mathematics K-8
- Block-of-time programs 7-8
- Social studies K-8
- Foreign language 7-9

Another change was the allocation of CDC budget funds for conferences on topics other than those already under study by districts. As a result new or experimental ideas could be investigated without a district having to commit itself to a year's study.

Notable during the second year were two conferences with nationally-known speakers, an improvement in the quality and substance of some of the annual reports, and the promotion of an NDEA summer workshop for teachers of disadvantaged children.

By the end of the year, the Council was apparently in the process of stabilizing membership. The college indicated its confidence in the organization through increased financial assistance in the form of professional and secretarial salaries.

Encouraging reports from many member districts indicated satisfaction with the growth which had taken place in staff members during the two-year period.

1715 2170

Two days later a directive was posted on the bulletin board and each Sergeant read it to personnel at roll call briefing. The order stated, "All patrol units from this date forward will enforce 2:00 am to 4:00 am parking in the residential area surrounded on the East and West by K Street and Indiana Street and on the North and South by 1st Street and Pierce Boulevard." The streets contained no posted warning signs to the effect that it was illegal to park cars in residential areas between 2:00 am to 4:00 am. Most of the citizens were unaware that such a law existed. The ordinance had been in effect for thirty years, but because of the work load and shortage of personnel and type of law, no attempt had been made to enforce it.

On the early morning shift thirteen patrol cars were used to handle the crime problem in Grandview. The whole Department deployed units according to the area need and amount of criminal activity. During the first week that the directive was in effect, a total of nine citations were issued. The Captain reissued his order with the qualification that orders would be complied with. The following week three citations were issued for 2:00 am to 4:00 am parking.

At the end of the secondweek the Captain called in all supervising personnel for a staff meeting. The discussion focused on non-compliance of orders by patrolmen. He cited

the 2:00 am to 4:00 am parking orders and demanded that each supervisor see to it that the men enforce his orders. Lieutenant Brown, a veteran of Grandview Station for 9 years, brought up the fact that the thirteen cars were too busy between 2:00 am and 4:00 am each morning to enforce the directives. Other administrators agreed. The Captain stated he anticipated this sort of argument and personally checked the activities sheet of each officer and found ample time to write parking citations. The other supervisors inspected the log sheets and agreed with the Captain.

That evening the briefing Sergeants made it clear to the patrolmen that the Captain wanted his orders followed. Several officers commented about the order and its affect on good police work and emergency situations. That morning the area cars were busy handling large gatherings of juveniles and numerous calls resulting in no citations being issued. Similar situations and required services occurred on Saturday and Sunday.

On Monday morning, Captain Bright was checking the weekend activities through the weekly summary form. He noticed that no citations were issued since his staff meeting Thursday. He immediately called the staff into emergency conference and demanded to know why his orders were not followed. Each supervisor presented the activity sheet of

of the patrol cars that indicated excessive amounts of criminal activity during the weekend. The officers patrol time in each case was well accounted for and there was never an indication on a log sheet that time was available to enforce 2:00 am to 4:00 am parking. Captain Bright made the statement that officers were padding the logs and the supervisors were supporting them in an effort to purposely defy him. The meeting was ended with no further comment on the situation.

Enforcing the Order

That afternoon an order was issued stating noncompliance with all directives would result in disciplinary action. Morale was at an all time low for the station. Officers complied at once by issuing 39 citations during the early morning hours for 2:00 am to 4:00 am parking. That number of citations continued for two weeks resulting in an increase in resisting arrest, interfering, insolence and insulting behavior. The burglary rate increased in the business area, especially between 1:00 am and 6:00 am causing the local businessmen to complain to the Captain for more police protection. Phone calls to the station increased by citizens wanting to know why their vehicle was cited for parking in front of their homes. Desk personnel were kept busy answering irate citizen complaints which frequently tied up the lines for emergency calls.

21986

Community Pressure Groups

Shift Lieutenants and Sergeants made inspections of residential parking affacted by the station order. It was evident that the officers were enforcing the law. The streets were almost vacant during the early morning hours while car thefts decreased to the lowest level in 5 years.

The local newspaper carried articles both pro and con on enforcing 2:00 am to 4:00 am parking. As a result, several citizen committees were formed to present their feeling about the situations. Mr. Sirmans and his group met with Captain Bright and expressed their approval of the enforcement action. He presented a letter to the station that stated the home owners in the area appreciated the streets being cleared of junkers and people sitting in cars during the early morning hours drinking and making noise. The letter was noted by Captain and posted on the Bulletin board.

Officers continued to enforce the ordinance. Apartment owners formed an association to protest the law because of the many renters who owned more than one car and had to park the extra vehicle on the streets. Their protests were heard at City Hall and by the Chief of Police. As a result, Inspector Fred Jones visited Captain Bright to discuss the situation. He presented the apartment owners complaint protesting enforcement of the parking ordinance and suggested to Captain Bright that it was his duty to enforce the law and displayed citizen

complaints requesting its enforcement The Inspector appreciated the situation, but indicated that discretion in enforcement is part of the administrative job. The meeting concluded with the Captain agreeing to re-evaluate the directive.

The following day Captain Bright posted a new parking directive, to the effect that strict enforcement was not necessary and citations should be issued as needed. No further explanation was offered or indicated by the Captain or his administrators.

During the last part of May and the first week in June, 1967, the patrol force cited every car that violated 2:00 am to 4:00 am parking. Pressure from groups within the community continued to mount. Several citizens had been cited five or six times for parking in front of their apartments. When they appeared before the judges in the local judicial district, many of the citations were dismissed. Court officers were swamped with the increase in citations that filled the Court Calendar and delayed many trials. Finally the District Attorney and presiding judge conferred with Captain Bright to clarify the issue. The Court indicated that because of many major civil and criminal matters and the cost and time it took the judges to dispose of the controversial parking cituation, most were being dismissed by the judges in the interest of justice. The Captain presented citizen complaints

APPENDIX

CASE OF THE 2:00 - 4:00 AM PARKING
CONTROL DIRECTIVE

Introduction

This case describes the affects of a policy imposed by a new administrator on an organization.* Some of his decisions are studied, the reasons for each decision, the forces that prompted the decision, and the problems generated by it. The case centers around a decision to enforce a malum prohibition law that had not been enforced until the administrator received a citizen's complaint.

Background

Captain Thomas A. Bright was transferred to Grandview Patrol Station in January, 1967. Prior to this assignment, he spent 4 years commanding the Central Jail; 3 years at the same facility as a Lieutenant; 3 years as a Traffic Sergeant; and 6 years working as a Patrolman. He received a baccalaureate degree from the state university in 1947 with a major in the social sciences.

Fellow officers regarded him as a competent man, somewhat quiet and reserved, able to think for himself, professional in his work but peculiar because he appeared to trust no

---

*The names of persons and jurisdictions used in this case study are entirely fictitious. The facts have been taken from an actual situation.

to justify enforcement action, but agreed that if most of the citations were being dismissed, he would direct officers to discontinue issuing citations.

Two weeks later Captain Bright was transferred to the Central Jail. He was replaced by Captain Jim Berg who eliminated rotating shifts and 2:00 am to 4:00 am parking directives. Morale increased and most transfer requests to other patrol stations were withdrawn.

Evaluation and Comments

The Captain's first administrative actions can be considered professionally justified, however, initiation of any administrative policy decision will result in similar resistance to change and create like problems in the initial stages of development. In turn, this case points out that any change in normally accepted practices requires internal cooperation prior to external cooperation and enforcement. Captain Bright failed to realize or appreciate the natural tendency to resist change.

A pressure group requested enforcement of an unpopular law. Captain Bright could have handled the complaint differently by considering the following alternatives: (1) avoid enforcing the 2:00 am to 4:00 am parking regulation; (2) provide conspicious patrol in the area of concern to discourage thefts and noise; (3) enforce the law; (4) enforce

the law, but issue warnings; and (5) enforce the law, but first condition the public and officers to the need for such enforcement. He chose the least acceptable alternative in making his decision. Any of the others would have resulted in less resistance.

When Captain Bright issued his orders, he did not properly prepare for the decisions. A staff meeting was called on several occasions to discuss the problem, but he failed to delegate the matter, thereby mistrusting others with responsibility to handle the complaint. He failed to realize that the best decisions are made by a staff group who affect the operational, policy making functions of the station.

Each directive or station order issued was written and posted for all to read. Resistance to change would have been minimized if some explaination or reason would have accompanied the order. Lines of communications must be open and policies of the department clear to those responsible for it. Policy in this matter was not clear.

The 2:00 am to 4:00 am parking law is another factor that played an important role. Numerous case studies indicate that malum prohibition law requires public support before enforcement can take place. The 2:00 am to 4:00 am parking law is definitely a malum prohibition law, quite unpopular

4. Internal acceptance of policy making decisions is necessary before external application can successfully take place.
5. Malum prohibition laws require public support before appreciable enforcement can take place.
6. Better decisions occur when they are made with the aid of a staff or persons concerned with the issues.
7. The administrator must consider departmental policy, the law and its precedence, special interest groups and factors affecting internal and external support in creating decisions.
8. Information concerning the "pulse of the community" is most difficult to obtain, therefore the administrator must have experience in predicting the reaction of the community to a given type of decision.
9. Any administrative decision that requires departure from established behavior must be programmed into acceptance by those affected.
10. Unless adequate explanation appears, operation policy decisions can be enforced and interpreted in as many ways as there are persons responsible for its implementation.

COLUMBUS, OHIO 43205

JAMES A. RHODES
GOVERNOR

WARREN C. NELSON
DIRECTOR

May 5, 19-Safety-9

TO: ALL STATE AND LOCAL W R A P COMMISSION AND COMMITTEE CHAIRMEN, MEMBERS - OHIO FEDERATION OF BUSINESS AND PROFESSIONAL WOMEN'S CLUBS

Dr. Ruth Morris, Chairman
W R A P Commission
1948 Cass Road
Toledo, Ohio 43614

Dear Dr. Morris:

This letter of gratitude, written to you, but directed to all "who may be concerned" - will also serve as a Foreword to our publication of the Patrol Defensive Driving Manual. As your group and associates meet at the annual convention of the Ohio Federation of Business and Professional Women's Clubs, we want all of you to know how grateful we are for your services toward our department's objectives. And we do hope for your continuing services in these efforts.

Although this Manual will be used by many groups, in addition to your Ohio Federation and W R A P Commission, we are happy to dedicate it to you and all of your associates, both on the state and local club levels. Of course, apart from this dedication, we have already made token expressions of our sentiments in the form of special certificates.

As you know, we have processed for you the Guidelines you prepared for sponsoring and administering Defensive Driving Courses. Previously we supplied you with samples of kits of materials available to leaders and to participants.

This Defensive Driving Course Manual, as you know was originally developed by a task group headed by Lt. Joseph A. Wolfe,*formerly with the State Highway Patrol, and now executive of the Safety Council of Columbus Area Chamber of Commerce. With his counsel we have prepared this latest edition. We are therefore grateful to him and his associates and to the Federation of Ohio Safety Organizations for their commendable services. As you know, suggestions are offered here for sponsoring both a four-hour and a three-hour course.

Also, as a complementary part of this Manual, we have had produced professionally the Chart (somewhat revised) used in the course. This too has been reviewed with Mr. Wolfe.

Our Research and Services staff planned and coordinated the production of all of these materials; and also did all of the necessary editing. A copy of the Course Manual and a Flip Chart will be sent to and earmarked for each Patrol Post - and to members of your Commission. A limited number will also be held by our department for other uses.

We wish all of you well!

Sincerely,

WARREN C. NELSON, DIRECTOR
Ohio Department of Highway Safety

SUBJECT: Driver Improvement Program

The Ohio Federation of Business and Professional Women's Clubs is to be commended for the presentation of this driver improvement program.

We are convinced that your efforts have contributed immeasurably toward the prevention of traffic accidents. We are also certain that your program will be effective in the future as a result of your dedication to furthering the cause for safety.

This constructive, educational traffic safety activity is an excellent example of accomplishment through determination of purpose and dedication of efforts that contribute to the safety of many people.

Very truly yours,

Robert M. Chiaramonte

GOVERNOR

FRED RICE
REGISTRAR

Dear Friends:

Because we have a mutual interest, that of traffic safety, it is a special pleasure to extend congratulations on your fiftieth year celebration.

The W R A P Commission and your Club W R A P Committees have put forth valuable services in behalf of traffic safety. These services are especially appreciated at the Bureau of Motor Vehicles since one of our duties is to collect the revenue for driver education through the issuance of driver licenses.

At anytime that we can be of service in any way, please feel free to call on us.

Sincerely yours,

FRED RICE
REGISTRAR

THE
OHIO
FEDERATION
OF
BUSINESS AND PROFESSIONAL WOMEN'S CLUBS

AFFILIATED WITH THE NATIONAL FEDERATION OF BUSINESS AND PROFESSIONAL WOMEN'S CLUBS, INC.

TO: Business and Professional Women of the Ohio Federation

SUBJECT: Women Responsible for Accident Prevention

The Ohio Federation of Business and Professional Women's Clubs is dedicated to citizen support through its program of civic participation. Our organization is honored to have such a responsible cooperative role presenting this Patrol Defensive Driving course to communities throughout Ohio.

In the presentation of this manual, we wish to extend our sincere gratitude for support to our Governor, the Honorable James A. Rhodes - to Mr. Warren C. Nelson, Director of the State Department of Highway Safety - to Colonel Robert M. Chiaramonte, Superintendent of the State Highway Patrol, whose service has been immeasurable - to Joseph A. Wolfe who as a State Highway Patrolman prepared and compiled the original version of this manual...and which is still basically similar in this edition to the original version - to Professor William E. Stuckey of the Cooperative Extension Service at the Ohio State University, for the outstanding service he gave us in helping to administer the original course - and finally to the Federation of Ohio Safety Organizations and its State Defensive Driving Coordinator, Mr. Harry R. Werner, Jr., Manager of the Toledo-Lucas County Safety Council for the tremendous help and continuing guidance he and his organization have given us. We thank the Federation of Ohio Safety Organizations for underwriting the cost of production of course instruction manuals for clubs these past two years.

Citizen education for accident prevention is the sole objective of WRAP as part of the total effort to reduce traffic accidents on our streets and highways. We appreciate the great need for responsible citizens to support existing enforcement and safety education measures. We intend to continue to so address ourselves to this objective.

Sincerely,

Ruth P. Morris

COURSE OUTLINE
DRIVER IMPROVEMENT PROGRAM
(County or Local Training)

LESSON	SUBJECT	TIME ALLOWED
Lesson One	Course Introduction - Orientation and Traffic Safety Problems.	20 Minutes
Lesson Two	Defensive Driving Defined	20 Minutes
Lesson Three	Safety Equipment - Mechanical Condition of Vehicle	30 Minutes
Lesson Four.	Laws of Nature	30 Minutes
Lesson Five	Defensive Driving Principles.	60 Minutes
Lesson Six	Freeway Driving	20 Minutes
Lesson Seven	Rules of the Road	50 Minutes
Lesson Eight	Summary	10 Minutes

ADDENDUM

(1) The OFFICIAL OHIO DRIVERS MANUAL used in the course, as well as other materials are obtainable from the Ohio Department of Highway Safety.

(2) This department also has available films that may be used to enhance the value of the course.

(3) At the completion of the course certificates of satisfactory fulfillment may be given - and these too are obtainable from the same source.

(4) The time sequences indicated here are adjusted to a total course span of four hours. However, depending on the needs of the particular group and the judgment of the instructor, the course may be broadened or diminished, but within reason.

(5) Generally speaking increase or reduction may be made in the discussion that follows the instruction presentation. See individual chapter notes for time reduction for three-hour course.

Traffic Accident Problem - Today and in the Future

The latest available statistics should be used. National and state figures may be supplemented with local figures to add interest and personal involvement.

The following data are shown in general approximations as of this writing. Steady increases in all areas are being experienced, however these basic figures should provide assistance to you in building interest in the course.

NATIONAL

Registered Vehicles	99,958,000
Licensed Drivers	105,700,000
Motor Vehicle Mileage	One Trillion plus
Accidents (1967)	13,700,000
Deaths	55,200
Injuries (1)	2,000,000
Economic Costs	$10,700,000,000
Death Rate (2)	5.5
Drivers Involved in Accidents (1967)	24,300,000

(1) Injuries causing disability beyond the day of accident. Less serious injuries: Another 2,000,000.

(2) Per 100 million motor vehicle miles traveled

GOVERNOR

STATE OF OHIO
OFFICE OF THE GOVERNOR
COLUMBUS 43215

May 5, 1969

TO: ALL MEMBERS ..... OHIO FEDERATION OF BUSINESS AND PROFESSIONAL WOMEN'S CLUBS

Dear Friends:

Fifty years of devoted effort on the part of an organization dedicated to the advancement of business and professional stature of its membership on the one hand - and active civic participation in the life of communities throughout our state ..... these are remarkable principles by which a group or individual can perpetuate worth to fellowmen.

Yet, these constitute what we might call the personal code of the Ohio Federation of Business and Professional Women's Clubs and its total individual membership. To use a hackneyed expression, not many can make this claim.

As the Governor of our great state, I am happy to congratulate all of you at this beginning of your second fifty years of service. Particularly here I take note of your services in behalf of life-saving measures in traffic safety.

Sincerely,

James A. Rhodes

JAMES A. RHODES,
Governor

DRIVER IMPROVEMENT PROGRAM
Leader's Guide

LESSON ONE:

Course Introduction - Orientation and Traffic Safety Problems.

Time:

Twenty (20) Minutes. (Reduce discussion time by 10 minutes for three-hour course.)

Objective:

To have students understand course content and importance of traffic safety knowledge.

Materials and Equipment:

Blackboard, chalk and eraser
"Ohio Accident Facts"

CONTENT AND METHODS

Notes

(This introductory lesson will be the only one in the entire course where class discussion potential is limited. In all other lessons it is highly recommended that instructor involve the students in discussion.)

Introduction

-- Instructor introduce himself and other participants or is introduced by representatives of sponsoring agency.

-- Have students introduce themselves giving names, city, county, organization and years of driving experience.

-- If time permits and class is small, list years of student driving experience on blackboard and total. Point out that their total experience and knowledge will be helpful in contributing to success of course.

Course Orientation

-- Review subjects to be discussed and time schedule for days activity.

-- Advise class that reference material will be passed out and explain procedure. (In most instances this material should be passed out after the lesson is completed.)

Appeal for Participation

-- Explain to class that lessons designed for student participation - show importance of:

- Participation in discussion.

- Asking questions.

- Future study and involvement.

Course Benefits to Students (These may vary with type of class)

-- Traffic toll serious national problem and inexcuseable.

-- Waste of most precious resources - lives and health of Americans.

-- Nine out of ten motor vehicle fatalities caused by driver or pedestrian error.

-- Learning arts and sciences of driving can prevent accident.

-- Information obtained from course will assist leaders -

- Basic qualifications of leader is ability to communicate.

The general committee throughout the year studied various reading programs and related topics. These included the Initial Teaching Alphabet, the Joplin plan, the linguistics approach, and others. The Osbornville plan, a locally developed modified Joplin plan arrangement, named after the school in which it originated, was evaluated by the committee.

A Glassboro State College faculty member worked as the CDC consultant with the district throughout its study. In the course of the year, committee members attended workshops and conferences sponsored by the CDC. Resource people were also called upon including Dr. Nila Banton Smith, Distinguished Service Professor in Reading.

Conclusions

By the end of the year, the committee reached a number of conclusions including the following:

Teacher enthusiasm appears to be an important ingredient in instructional success.

Interaction among teachers at committee meetings is an important method for educational sharing.

There does not appear to be a genuine difference between the vocabulary and comprenension skills of our fourth through eighth grade students.

Based upon results of the Gates Reading Survey, our students generally tend to conform to normal expectations while the lowest quarter contains fewer pupils than expected.

All teachers have some responsibility for the improvement of their students' reading.

Recommendations

These conclusions led the committee to make several recommendations to the local administration:

Preventive and remedial action, to be emphasized at grade levels three and four, should be considered as one approach to aiding readers with potential learning problems.

Remedial and developmental reading experiences should continue to be expanded, particularly at the secondary level.

Subject-matter teachers can do much to insure progress by students in their particular field, if they will teach effective use of the textbook and have a supply of supplementary materials readily available.

Results of the Gates Reading Survey should be made available to all instructional leaders in the district.

The reading improvement study, in affiliation with the Curriculum Development Council, should be continued for another year.

The Process

The pattern of group process seemed almost classic as the committee met during the year. The chairman understood principles of group dynamics, felt he had a strong committee, and did not hurry things. When some classroom teachers complained of "too much brass" attending committee meetings, he took care of the matter. Although chairman and consultant both doubted the workability of the sub-committee plan proposed after considerable discussion by the committee, they accepted it. Having "tested" its leadership's sincerity, the committee settled down to hard work, found its direction, and moved.

2172

STATE

Registered Vehicles	6,050,000
Licensed Drivers	7,000,000
Motor Vehicle Mileage	52,800,000,000
Accidents (1)	220,000
Deaths	2,555
Injuries	110,000
Economic Cost	$510,000,000
Death Rate (2)	4.8
Drivers Involved (3)	390,000

(1. Reported Accidents only)
(2. Per 100 million motor vehicle miles traveled)
(3. Excludes drivers of legally parked vehicles)

Based on prior experience, it has been predicted that by 1975 there will be approximately 125 million licensed drivers in the United States; registered vehicles, 117 million, and vehicle miles of travel, 1.24 trillion.

Current mileage death rate trends indicate at least 54,000 traffic deaths can be expected in the U.S. by 1975, unless there is a substantial increase in accident prevention efforts.

22005

Review Qualities of an Expert Driver (See Chart #3)

Notes

Expert driver . . . . knows:

-- What to look for.

-- How to insure seeing it.

-- How to comprehend its significance.

-- How to be in a position that will give him time for safe action.

(Chart #3 available for visual summary.)

Five Seeing Steps (See Chart #4)

Since "seeing" is important to defensive and expert driving review the following five steps and supplement remarks by drawing appropriate sketch on blackboard.

-- Aim high in steering.

-- Get the BIG picture.

-- Keep your eyes moving.

-- Leave yourself an out.

-- Make sure they see you.

(Chart #4 available for visual summary.)

Summary of a Defensive Driver . . . He is a: (See Chart #5)

-- Traffic hazard detective.

-- An analyst and evaluator.

-- Good communicator.

-- Good samaritan
in other words he is a:

-- Nib nose.

-- Cynic.

-- Gossip.

(Chart #5 available for visual summary.)

Suggest ending session on humorous note by showing Chart #6.

Shows that more people are getting loaded than box cars.

22008

DRIVER IMPROVEMENT PROGRAM
Leader's Guide

LESSON THREE:

Safety equipment and mechanical condition of vehicle.

Time:

Thirty (30) Minutes. (Reduce discussion time by 10 minutes for three-hour course.)

Objective:

Acquaint students with importance of proper safety equipment and good mechanical condition of vehicle.

Materials: (See Charts #7 and #8)

Grab box of safety equipment.
Equipment for demonstrating seat belt effectiveness.
Diagram of vehicle inspection points.
Charts 7 and 8 (baseball catchers)
Blackboard, chalk, eraser
SMV Emblem Brochure.

CONTENT AND METHODS

Notes

Safety Equipment

Have a box containing the safety equipment that should be carried in the car. After appropriate remarks regarding importance of such equipment, remove the equipment from the box, a piece at a time, and discuss:
(Introduce with Charts 7 and 8 -- needed for protective equipment)

-- Flare

- A 15 to 20 minute red flare to be used when car is disabled at night. In addition to slowing traffic, the flare will provide light for changing tire.

-- Flashlight

- When trouble occurs, can be used for seeing about the car or for flagging traffic.

-- First Aid Kit

- Someone should be trained to give proper first aid.

-- Litter Bag

- There's a law against littering. Then, too, it's safer to put litter in a bag than it is to turn down window to throw it out.

-- Window Scraper

- Many accidents occur because vision is obstructed.

-- Sideview Mirror

- This, in addition to a glare-proof rearview mirror; but remember we still have a blind spot.

-- Sand

- A small box to give traction in case of ice may keep us going safely.

-- Slow-Moving Vehicle Emblem (SMV)

- For vehicles which normally travel 25 miles per hour or less.

Notes

-- Seat Belts

- Demonstrate principle of seat belts -- that is -- objects on the inside of car will continue to travel at same speed of car, if car stops, unless fastened down.

-- Others

- Fire extinguisher.
- Bumper strips.
- Tire chains.
- Tire changing tools.
- ? ? ?

Mechanical Condition of Vehicle:

Now discuss importance of good mechanical condition of vehicle. Volunteer checks and State Patrol Inspections indicate about 20 percent of vehciles on our highways have one or more defects.

Ask student to list points to inspect and discuss the "why" of each point.

-- Points to Consider

- Brakes - Two checks should be made. First, with car standing still, apply full pressure on the foot brake pedal. There should be at least one inch between the pedal and floor board when brakes are fully applied. Second, set hand brake and put car in gear and attempt to move forward. Hand brake should hold against engine pull.

- Lights - This check should include headlights, parking lights, turn signals, tail lights, stop lights and back-up lights.

- Steering - Excessive play in the steering wheel makes steering difficult. Turn wheel back and forth to determine play. Check tie-rod couplings. Excessive toe-in or toe-out and broken springs should be noted.

- Tires - Smooth rubber, cracks, and cuts, fabrics showing through, and presence of nails in tires should be eliminated.

Notes

- Exhaust - Muffler and tail pipe should be free of cracks and leaks. Loose or broken couplings should be corrected.

- Glass - All glass should be free of cracks and discoloration. Windshield should be free of stickers.

- Windshield Wiper - Turn on windshield wiper to make sure it operates. Check blades for deterioration.

- Rear View Mirror - Should be in place and free from excessive vibration.

- Horn - Sound horn.

DRIVER IMPROVEMENT PROGRAM
Leader's Guide

LESSON FOUR:

Laws of Nature

Time:

Thirty (30) Minutes. (Reduce discussion time by 10 minutes for three-hour course.)

Objective:

To inform students regarding the relationship of laws of nature to safe driving.

Materials: (See Chart #9)

Blackboard, chalk and eraser.
Small object attached to rubber band to demonstrate centrifugal force.
Chart #9 listing chances of being killed in collision.
Stopping distance charts.

DRIVER IMPROVEMENT PROGRAM
Leader's Guide

LESSON TWO:

Defensive Driving Defined.

Time:

Twenty (20) Minutes.

Objectives:

Have student understand the meaning and importance of Defensive Driving and its relationship to accidents.

Materials:

Charts 1, 2, 3, 4, 5 and 6.
Blackboard, chalk and eraser.

CONTENT AND METHODS

Notes

(Involve the students in the discussions whenever possible. Remember its easier for you to tell them the answer but more interesting and acceptable if they participate in solving the problems.)

Is it Possible to Operate a Vehicle Safely in Today's Traffic?

Yes - Professionals (truck drivers, bus drivers, etc.) with some rare exceptions, have reduced their accident rate per 100 million motor vehicle miles from 36 to 12.

Discuss Preventability of Accidents - (Get Views of Class.)

-- Are all accidents preventable - by whom?

-- Have class define preventable accident.

- If there is anything either driver could reasonably do to prevent it, no matter what conditions exist, it can be classified as preventable.

-- Review conditions (if time permits). (Road, weather, attitudes, physical and mental fitness.)

How Can Accidents be Avoided? (See Chart #1)

By drivers becoming skilled drivers.

-- Knowing HOW to handle a car. (Physical Skills)

-- WHAT to do.)
-- WHEN to do it.) Laws of man and laws of nature.

Drive Defensively.

(Summarize by showing Chart #1 which contains above listed information.)

Define and Explore Qualities of Defensive Driver. (See Chart #2)

One who expects the unexpected - recognizes driving hazards and adjusts to them.

-- Observes all laws (nature and man made) and road ethics.

-- Allows for lack of skills and knowledge on part of other driver.

-- Makes concessions to avoid collisions (concedes right-of-way.)

-- Recognizes common hazards.

-- Not caught at last minute making futile attempts to avoid accident.

-- Defensively alert to avoid accident traps.

Notes

Centrifugal Force

All moving objects have a tendency to travel in a straight line. When this tendency impels an object from a center of rotation it is called centrifugal force. By application of a stronger counter force this tendency can be controlled.

Demonstrate centrifugal force - attach small object to rubber band and whirl. Note how object tends to pull away. As the speed of the whirling motion increases the pull on rubber band increases. The pull is centrifugal force. The rubber band acts as a counter force and is called centripetal force.

Use blackboard to explain how centrifugal force, friction and speed affect a vehicle rounding curve.

Inertia

Tendency of object at rest to remain at rest and an object in motion to continue moving in a straight line.

Use seat belt principle as example.

Energy

-- Ability to do work.

- Potential energy.
- Kinetic energy.

-- Potential Energy:

- Stored energy - gas in tank is stored energy when ignited by spark it becomes kinetic.

-- Kinetic Energy:

- Energy of motion - greater the speed of object, the greater its kinetic energy and momentum.
- It's a measure of how long a motion of an object persists.

  (Example - distance car moves after accelerator pressure released.)

- Varies as the square of the speed - if you double speed of car (30 mph to 60 mph) you quadruple the amount of kinetic energy (takes four times as far to stop.)

Gravity

-- Downward pull. Natural force that causes objects to be pulled toward center of earth.

-- The amount of pull is called weight.

AN OVERALL EVALUATION

This interim overall evaluation of the work of the Curriculum Development Council program, 1963-65, is based on annual district reports, evaluations conducted at the various conferences, and the direct observations of the executive secretaries.

Some Council Successes

1. Fine support of the idea from college staff members and school district leaders in the experimental period.*
2. Enthusiastic attitudes toward curriculum change among classroom teachers in many Council schools.
3. Maturity of thinking on the part of many school superintendents in recognizing realistic goals in curriculum development.
4. Leadership improvement sessions which served to inspire local Council chairmen and clarify their roles.
5. The fine work of many consultants of high caliber and dedication.
6. Growth in the ability of schools to use consultant service profitably, accompanied by growth in the ability of consultants to apply their skills.
7. The publication of handbooks, bulletins, and annual reports.
8. Continued development of an excellent working relationship between the college and the public schools.
9. Improvement effected in schools as a result of the Council operation.

Some Unsolved Problems

1. The need for more careful selection of study topics limited to tangible goals appropriate to the local school situation.
2. The need for public school staffs to realize that curriculum revision is an on-going, continuous effort, not concluded at the end of a study.
3. The need to produce meaningful results in order to convince local school boards of the importance of adequate finances for action research.
4. The need for a continuing leadership program for local chairmen and consultants.
5. The need for better communication between local study committees and the total school staff.
6. The need to find better ways for Council districts to share their curriculum improvements with others.
7. The need for increased Council staff to insure more comprehensive service and help to member districts.
8. The need to draw further on the abilities of the College Resource Board.

*The writers wish to pay tribute to the preparatory committee members from the Glassboro State College staff, whose help was so valuable in the formation and achievements of the Council: Dr. Lawson J. Brown, Dr. Horace T. Keller, Dr. Stanton B. Langworthy, Dr. Lawrence E. Smith, and Dr. V. Eugene Vivian; and to the presidents of the Council, Superintendents Paul Jones of Cherry Hill Public School District, Lawrence R. Winchell, Jr., of Margate City Public Schools, and Herbert Gansz of Deptford Township Public Schools.

2173

Notes

- Pull of gravity is stronger when driving down hill than on level. This will increase kinetic energy (motion) and increase stopping distance.

Center of Gravity

-- In auto there is a point on which the whole weight is centered - a point at which distribution of weight will evenly balance off pull of gravity.

- The higher this center the more likely the car is to tip.

- Automotive engineers have lowered this center.

- Adding weight (luggage, etc.) on top raises this center.

Force of Impact

-- Amount of force with which two or more objects are brought together.

-- Measured by pounds - determined by speed of object and resistance moving object encounters.

- Driver can control speed but not weight. (fixed factor)

- Resistance varies with "give" of object. (stone wall vs bushes)

- When you double speed the force of impact increases about nine times.

-- Chart #9 shows chances of being killed at various speeds.

MPH	ODDS
21 - 30	1 out of 317
31 - 40	1 " " 98
41 - 50	1 " " 89
51 - 60	1 " " 32
61 - 70	1 " " 8
over 70	1 " " 3

Review Stopping Distance. (Pass out stopping distance charts.)

Speed - feet traveled per second - reaction time - braking distance - total stopping distance.
(Use dollar bill to demonstrate reaction time.)

22016

CONTENT AND METHODS

Notes

The material covered in this session is important to driving but can be very technical. Instructor should make every attempt to simplify this material. Use of blackboard and illustrations to explain important points is recommended.

Friction

A. If you push or slide one object over another you feel a force which opposes your attempt. This resistance to motion of one object pressing or sliding against or over another is called friction.

-- If you rub dry hands together there is more resistance than if hands were wet or soapy.

-- If pressure is applied to hands there is more resistance than if palms held together loosely.

(Ask students to experiment by rubbing hands together.)

B. Friction is neither good or bad - depends on how used.

-- Without friction we could not control car - need it to start, speed up, slow down, turn, stop.

-- If this force used improperly it can cause skid.

C. Coefficiency of Friction

-- Is a measure of frictional force available for controlling the vehicle.

-- Two types - sliding and rolling.

- Some sliding friction has less coefficiency than rolling.

- Stopping distance longer when skidding.

- Generally coefficiency greater if car slowed to a stop.

- The higher your coefficiency of friction the greater is control over the car.

-- Factors affecting coefficiency:

- Speed - lowers friction. At high speeds coefficiency may be only half of that at normal speed.

- Tires - smooth thread reduces friction.

- Road Surface - texture of road, wet pavement, snow and ice affect the coefficiency of friction.

DRIVER IMPROVEMENT PROGRAM
Leader's Guide

LESSON FIVE:

Defensive Driving Principles.

Time:

Sixty (60) Minutes. (Reduce discussion time by 10 minutes for three-hour course.)

Objective:

Develop among the students an appreciation and understanding of the principles and techniques of defensive driving.

Materials: (See Chart #10)

Blackboard, chalk, eraser.
Chart number ten (10). How to avoid being hit from the rear.

CONTENT AND METHODS

Notes

Review Defensive Driving Principles

-- Trust no one - expect the unexpected.

-- Look for traffic hazards.

-- Communicate with others.

Test Knowledge of Class on Most Prevelant Types of Accidents

Before class begins, list the underscored words on blackboard and have class guess which type account for the most and least number of fatalities - then insert correct figures as follows:

Collision with non-motor vehicle (train, bike, animal, fixed object, etc.)	12.9%
Collision with pedestrian	17.2%
Non-collision - ran off road, etc.	28.2%
Collision with another motor vehicle	44.7%
Total	100 %

Review Six Positions Another Vehicle Can Take in Relation To Your Car Prior to Crash. (List on blackboard as discussed.)

I. Car in front of you
2. Car following you
3. Car approaching you from opposite direction
4. Car approaching you from angle
5. Car passing you
6. Car you are passing

Review Defensive Driving Procedures Used to Avoid Collision With: (Use of blackboard diagrams strongly recommended for rest of lesson.)

CAR IN FRONT OF YOU

-- Review safe following distance rule. (One car length for every 10 mph.)

- Review reaction distance - braking distance - stopping distance.

DRIVER IMPROVEMENT PROGRAM
Leader's Guide

LESSON SIX:

Freeway Driving.

Time:

Twenty (20) Minutes. (Reduce discussion time by 5 minutes for three-hour course.)

Objective:

To have students develop an understanding of proper freeway driving techniques.

Materials:

Blackboard, chalk, eraser.

-- Causes of this type of accident.

- Inattention.
- Excessive Speed.
- Following too closely.
- Poor maintenance. (brakes, etc.)

-- Clues to look for:

- Brake lights or signals.

- Traffic congestion ahead.

- Tavern or motel ahead.

- Police officer ahead.

- Pretty girl walking down street.

- Ball rolling onto street or dog running across street.

- Children playing on walks.

- Pedestrian preparing to cross street.

CAR FOLLOWING YOU

-- What usually happens in this type of accident? (Suggest use of blackboard to depict accident.)

- Driver number one noting slow moving vehicle (farm tractor ahead) - applied brakes suddenly.

- Driver number two did not see slow moving vehicle failed to stop and crashed into vehicle number one and farm tractor.

- Was rear driver at fault? Possibly.

- Could it have been averted? Whose responsibility?

-- Re-enact accident on blackboard.

- Review stopping distance. (50 mph at 3/4 second reaction time = 55 feet during reaction period - 138 feet during braking period.)

- Diagram showing how lack of communication by number one caused driver number two to react 3/4 second and 55 feet later causing accident.

Notes

-- How to avoid being hit from rear?
(Summarize on Chart #10.)

- Signal well in advance of stops, turns, or lane changes.

- Stop gradually over a long distance, giving following cars more time to react.

- Flash brake lights when standing or moving slowly to warn high-speed vehicles coming from the rear.

- Keep pace with traffic within limitations of conditions and speed limits.

- Adjust inside and outside mirrors to give best possible view of the rear.

- Keep a check of vehicles in the rear.

- Avoid cruising in the blind spot of car just ahead in adjacent lane.

- Get rid of tailgaters by arranging for them to pass when it is safe.

- Raise hood if car is stalled and can't be moved out of a traffic lane. Turn on signal lights as an additional warning, especially if both right and left can be set to flash together. If not, some authorities think it is better just to use tail and dome lights.

- Never change your mind suddenly.

VEHICLE APPROACHING POSITION

-- Head-on collisions are extremely serious. Two cars approach each other at a speed equal to the sum of their speeds - if they collide, the impact is terrific.

- Only thin paint line separates the two. At times both drivers are inches from eternity.

- Keep away from centerline - plenty room on right.

- If other driver crowds or crosses line - give ground don't die fighting for your right-of-way.

-- Round Curves Expertly

- Stay in own lane - on own side of road.

- Decrease speed prior to entering curve - negotiate curve under power to overcome centrifugal force. (re-emphasize centrifugal force vs friction.)

-- Left Turns

- Signal intentions ahead of time - not after stopped.

- Position vehicle near center of road.

- If stopped, keep wheels straight ahead.

- Yield to approaching traffic.

-- Clues Review (Look for clues - don't trust anyone.)

- String of cars coming towards you - all out to get you. Where will you go.

- Large truck coming towards you - cars behind truck. One may be following too close and veer into your lane to see.

- Child on bike followed by cars - vehicle driver may pass bicycle and come into your lane.

- Driver approaching you at intersection has right turn signal on. What if he turns left? Are you prepared?

VEHICLE APPROACHING FROM ANGLE - INTERSECTION ACCIDENTS

-- Review dangers of intersection travel.

- Area of greatest traffic conflict. One-fourth of all traffic accidents occur at intersections and one-half the urban traffic deaths occur there.

- Indecision of drivers.

-- Four Point Plan for Intersection Safety - Know - Slow - Show - Go (Copy on blackboard)

KNOW

-- Drivers do unexpected things at intersections. They --

- Turn abruptly - often from wrong lane.

- Signal improperly - or not at all.

Note

- Stop suddenly - without warning.

-- Know in advance where you want to turn or what you want to do at intersections.

- Watch for map landmarks.

- Next exit signs.

- House numbers.

- Sudden last minute swerves cause pile-ups.

-- Know that traffic signs and signals only regulate traffic - they don't guarantee right-of-way.

- Obey them but be prepared to yield.

- Be cautious of traffic control devices that permit you to make your own decisions. (Yield, right-of-way signs, caution signals.)

- Be sure your decision is a safe one.

-- Know rules of right-of-way but don't die fighting for them.

-- Know your stopping distance - a critical matter at intersections - be prepared to stop.

- Know your reaction - braking and stopping distance formula.

- Remember on wet pavement it takes longer to stop.

- On ice, it takes up to ten times further to stop.

SLOW

-- Slow down for intersections - no place to speed-- your seeing distance is as important as your stopping distance.

- Slow down gradually.

- Never speed up to beat a light - may have to stop suddenly.

-- Have your foot off accelerator and over brake pedal - give yourself that extra split second reaction time.

-- Look to the left first, then right. Traffic from left is closest to you, crosses your path first - take second look.

SHOW

-- Show others what you intend to do - where you intend to go. Show by getting into proper lane.

-- Use turn signals at least a half block away.

-- To turn right get close to curb - watch for bicycles and pedestrians.

-- Don't try to beat oncoming traffic - pedestrians.

-- Keep wheels straight while waiting to make turn.

-- Check mirrors to see if others aware of your intentions.

GO

-- Go when sure. Get through intersection without hesitation. Over caution confuses others.

-- Go easy when light changes. Somebody may try to beat the signal.

-- Don't tailgate another car - something you can't see may make him hit brakes.

VEHICLE PASSING YOU

-- How Do You Feel When Vehicle Passes You? (Discuss)

- Emotional reaction - resentment?

- Reflection on your driving ability and capabilities of your car?

- Passing is a normal driving experience - no need to react emotionally.

-- What is Wrong When Too Many Vehicles Pass You? (Discuss)

- Speed too slow for traffic.

- Dangers of traffic stacking up behind us - impatient drivers - risky passes.

- Pull off road to allow traffic to go by.

- Discuss dangers of waving traffic on.

-- Dangers Involved in Vehicle Passing You (Discuss)

- Sideswipe - cut in - run off road.

Notes

-- Traffic Situations Which Involve Being Passed (Discuss)

- Normal straight away driving.
- We may attempt to change lanes when another vehicle is overtaking on the right or left.
- We may be attempting to make a right turn.
- We may be pulling from a parked position.

-- Defensive Driving Rules to Remember When Being Passed (Discuss)

- Don't race - slow down and make it easy for other fellow.
- As soon as you realize you are being passed, check oncoming traffic - then slow down and give the passing car room to get back in line in front of you.
- Check the rear before changing lanes. Check mirrors and look back at the blind spot. Use turn signals then move over when lane is clear.
- When turning right - get into proper lane early - stay close to right hand curb to block right hand passes - use signals early.
- When coming out of parking space - don't nose out to look for oncoming traffic - take a good look before you move - wait for break in traffic - then pull out promptly.

VEHICLE YOU ARE PASSING

-- Discuss Reasons for Passing

- Other vehicle too slow.
- Emotional reaction - hate to follow other vehicle.

-- Is There Anything Wrong With Passing? (Discuss)

- Should be done with consideration and courtesy.
- Can cause sideswipes, head-on collisions, or run-off-road accidents.
- Nothing wrong if legal and done carefully.

-- What Do We Gain By Passing? (Discuss)

- Best to get into stream of traffic and stay there.
- Always ask yourself "Is this pass necessary?"
- It is legal - it is optional - sometimes desirable and necessary.

-- Places You Don't Pass (Discuss)

- Curves, hills, Railroad Crossings, Intersections, etc.

-- Four Conditions to Consider Before Passing (Discuss)

- Speed of your vehicle.
- Speed of vehicle being passed.
- Speed of oncoming vehicle.
- Distance of oncoming vehicle.

-- Things You Should Do To Insure Safe Pass (Discuss)

- Check rear view mirror - and blind spot
- Sound horn.
- Pass as quickly as possible.
- Pull back when you have sufficient clearance.

-- Good Passing Rule to Remember -

"When in Doubt, Don't"

CONTENT AND METHODS

Take a few minutes to discuss the changes taking place in our highway system. Point out that many of the defensive driving principles are the same on freeways as on ordinary highways. However, there is a major difference -- high speed. These straight, ribbon-like, concrete freeways save time and expense. Experience proves there are fewer accidents on these roads, but the accidents which do occur are big ones, usually involving three or more cars.

Not

Entering the Freeway

Purpose of acceleration lane:

-- Allow blending in with normal flow of traffic.

-- Stops are dangerous and cause rear-end collisions on acceleration lane and the freeway proper.

-- Freeway driver also has obligation -- he should cooperate by --

- Slowing down to create gap for entering vehicle.

- If traffic permits, he should move into left lane.

Driving on Freeway

-- Pick lane and stay with it.

-- Move with traffic, show speed can result in rear-end collision.

-- Follow at safe distance, remember your speed is greater, requiring longer stopping distance.

-- When passing, look before you start your movement and communicate your intentions.

-- Avoid monotony --

- Turn on radio.

- Vary speed as traffic permits.

- Open window for fresh air.

- Change sitting position.

- At night change light intensity on instrument panel.

- Stop every 75 - 100 miles for gasoline or refreshments.

- If all this fails, stop and sleep. Fatigue can result in disa

22027

Notes

-- Slippery spots at overpasses and bridges.

-- Disabled car?

- Pull off on shoulder.
- Raise hood.
- Tie handkerchief on aerial or door handle and wait for assistance.
- Don't walk or hitchhike.
- At night put on dome and flasher lights.

Getting Off Freeway

-- Plan your trip. Know the name and appropriate location of your desired exit.

-- Get into proper lane early.

-- Signal intent to leave as soon as you slow down.

-- Adjust your speed to normal highway speed and conditions.

LESSON SEVEN:

Rules of the Road.

Time:

Fifty (50) Minutes. (Reduce discussion time by 15 minutes for three-hour course.)

Objective:

Have students more completely understand the rules of the road.

Materials:

Blackboard, chalk and eraser.
Driver's Manual.
Who's Right - Who's Wrong cases.

DRIVER IMPROVEMENT PROGRAM
Leader's Guide

LESSON EIGHT:

Summary.

Time:

Ten (10) Minutes.

Objective:

Summarize Course - issue challenge.

Materials:

None.

CONTENTS AND METHODS

Use your own judgment on how your particular course should be summarized.

One approach could be to have students feed back to you one important item they got out of the course.

Summary should include a recap and challenge.

FOREWORD

This Teacher's Guide, *Highway Drawing*, is one of a series in the Highway Technicians Program. This program was initiated by the New York State Department of Transportation (formerly the Department of Public Works) to help relieve the shortage of highway technicians. As a result of their initiative the first editions of Units I through V were published, starting in 1961.

John L. DeLee, now Principal Civil Engineer in the Bureau of Highway Planning of the Department of Transportation, planned the original series of nine units with the help of other personnel from the district offices. Edward Umiker, now Associate Civil Engineer in the Buffalo District Office of the Department of Transportation, and Ralph Fimmano, Senior Civil Engineer in the Utica District Office, collaborated in developing the topical outlines for the nine units.

Early in 1967 Philip E. Hagerty, Assistant Administrative Deputy of the Department of Transportation, called for a renewed effort to complete all the units planned in the program and to update as needed those already published. As a result, several Department engineers were made available as consultants to the New York State Education Department to do the writing needed in completing and updating the whole series.

The first edition of the present Guide (published in 1961) was written by Ralph Fimmano, under the guidance of Berton P. Plummer, Associate in the Bureau of Occupational Extension and Industrial Services of the Education Department. Frank E. Howard, former Associate in the Bureau of Vocational Curriculum Development and Industrial Teacher Training, also cooperated in the production of the 1961 edition. As part of the renewed effort to complete the program, Mr. Fimmano made the present revision. Nelson S. Maurer, Associate in the Bureau of Continuing Education Curriculum Development, supervised the revision and preparation of the final manuscript for publication.

To all the agencies and individuals mentioned above, this Bureau makes grateful acknowledgment for the responsibilities which they so faithfully fulfilled.

HERBERT BOTHAMLEY, *Chief*
Bureau of Continuing Education Curriculum Development

WILLIAM E. YOUNG, *Director*
Curriculum Development Center

INTRODUCTION

The rapid expansion in the building of state and Federal highways has caused a serious shortage of qualified technicians and engineers for planning, supervising, constructing, and maintaining highways. The New York State Department of Transportation and the State Education Department have collaborated in planning the Highway Technicians Program to overcome this shortage.

This program is expected to help provide the additional technicians and engineers by upgrading people employed in the lower-level technical jobs. This Teacher's Guide, *Highway Drawing*, and the others in the program are intended primarily to improve the skills and technical knowledge of those technicians.

Local boards of education and other sponsors of adult education programs are being encouraged to offer the courses in this program as part of occupational education. Besides attracting students from the Department of Transportation in the job categories mentioned above, students will also be drawn from the public works departments of counties, cities, and towns; in addition technicians, estimators, and junior engineers employed by construction contractors will be found in these classes.

The units of the Highway Technicians Program have been planned to be taught in numerical sequence. Enough subject matter has been included in each lesson for about 2½ hours of classroom instruction. The total length of the course, however, may be adjusted to fit in with the prior experience and education of enrollees.

The units in the Highway Technicians Program are:

Unit I. Basic Mathematics Review
Unit II. Highway Drawing
Unit III. Highway Surveying
Unit IV. Preliminary Highway Planning
Unit V. Soils and Drainage
Unit VI. Highway Design and Estimating
Unit VII. Highway Construction and Inspection
Unit VIII. Highway Structures
Unit IX. Highway Maintenance

EDWARD L. BOOTH, *Chief*
Bureau of Occupational Extension and Industrial Services

C. THOMAS OLIVO, *Director*
Division of Industrial Education

CONTENT AND METHODS

Notes

In Lesson Four we discussed the laws of nature and their effect on safety. Let us now consider the laws of man.

Point out these laws are made for our protection.

It behooves all of us to know and abide by these laws.

Use the cases in the Who's Right - Who's Wrong mimeograph to stimulate discussion.

Introduce the Who's Right - Who's Wrong discussion by relating the three kinds of drivers responsible for our accidents:

1) Those who can't - physical limitations.

2) Those who won't - attitudes.

3) Those who don't know - Do you know the rules of the road? Use cases to find out.

WHO'S RIGHT - WHO'S WRONG?

Accident cases, with answers as interpreted from The Ohio Motor Vehicle Code.

CASE I: Car A is driving 40 miles per hour on the inside lane of a four lane roadway with marked lanes. You approach from rear to pass.

After following Car A for some time, you see that the driver is not going to give way to the right, so you start passing on the right.

Car A then proceeds to give way to right, colliding with your car.

Who is right - who is wrong?

ANSWER: Driver of Car A is wrong. The law provides that when outside a municipality, you may pass to right or left providing lanes are clearly marked and this move can be made with safety. However, if lanes are not marked, you shall pass on left only. Inside a municipality, you may pass on either side if traffic is moving in two continuous lines in the same direction and this move can be made with safety. Whenever changing lanes, a driver must ascertain that such movement can be made safely.

CASE II: You are going west on Route 40, west of Columbus, (on a four lane divided highway) at a rate of 45 mph. A school bus going east stops to unload children. As soon as you see the flasher lights on the bus, you apply your brakes and come to a sudden stop without giving arm signal.

Notes

Car B, following, cannot stop and collides with your car.

Who is right - Who is wrong?

ANSWER: In this case there are three phases of traffic law, stopping for school bus, signaling intention to stop, and stopping in assured clear distance ahead.

When a school bus stops on highway outside a municipality for the purpose of loading or unloading, drivers of all vehicles must stop at least 10 feet away from front or rear of bus, unless the highway has been divided in two roadways, separated by a physical barrier. Then, only the driver operating on the same roadway must stop. In this case, you did not have to stop, but it was legal to stop providing you gave the proper signal.

The driver of Car B was negligent inasmuch as he failed to stop within the assured clear distance ahead.

CASE III: Car A suddenly slows down to turn to the right without giving a signal. Car B, following, cannot stop, so he swerves into left lane to avoid Car A.

Car B collides head on with Car C, coming in opposite direction at a speed of 68 mph.

Who is right - Who is wrong?

ANSWER: In this case, driver of Car A did not give proper signal. Driver of Car B failed to stop within the assured clear distance ahead and drove into left lane of traffic when that lane was occupied. Driver of Car C, according to your statement, was driving 68 mph, thus exceeding the speed limit. Therefore, all three drivers were wrong.

CASE IV: You approach a through highway and stop in obedience to a stop sign. You see Car B coming, but he is way down the road, so you proceed. Car B collides with you and the investigation of the accident shows Car B to be travelling at a speed of 75 mph.

Who is right - Who is wrong?

ANSWER: The law states that when intending to enter a through highway, the driver shall stop, in obedience to a stop sign, and shall yield right-of-way to all other vehicles who are not obliged to stop. You were wrong because you did not comply. Driver B was exceeding the speed limit. So both drivers were wrong.

CASE V: You approach from the rear a car travelling at 20 mph. You try to pass several times but cannot.

Notes

So, you take a chance and try to pass, but you collide with a car going in the opposite direction.

Who is right - Who is wrong?

ANSWER: You attempted to pass when the left lane was occupied; thus, you are in violation. Driver of the car going 20 mph on a highway with heavy traffic was wrong. He was obstructing the natural flow of traffic.

CASE VI: It is 11 o'clock at night and raining hard. A truck without a tail light is driving ahead of you but you don't know it. You are driving at 45 mph on a road with a speed of 50 mph. You are blinded by the lights of an approaching car which did not dim and you collide with the truck.

Who is right - Who is wrong?

ANSWER: First of all, just because you were driving 45 mph on a road marked "50 mph", does not mean that you were not driving too fast. You should always adjust your speed to conditions. The driver of the truck did not have a tail light. The law requires that any vehicle using the highways at night must have a light on the rear, that can be seen 500 feet. Driver of the approaching car did not dim, thus he was in violation. You must dim your light when meeting oncoming vehicles. So, all were wrong.

CASE VII: You are involved in an accident which resulted in more than $100 property damage. You call the state patrol and they investigate and make their full report. Two months pass and you receive notice that your driver's license has been suspended for failure to report the accident.

Who is right - Who is wrong?

ANSWER: Even though an accident is investigated by an enforcement official, it still does not relieve the driver of the responsibility of reporting this accident to the Ohio Department of Highway Safety. The Financial Responsibility Law states that if there is personal injury or property damage in excess of $100 to either car, the accident must be reported within five days, on a form provided. In this case, the driver apparently assumed the report made out by the State Patrolman was sufficient. This is not true. The report form and information can be secured from any enforcement official.

SUMMARY

In all these cases the question is asked: "Who's Right and Who's Wrong?"

It doesn't really matter who is right and who is wrong if you're dead, right or wrong! So we must all remember not to be completely satisfied and at ease because we ourselves are obeying all traffic rules and regulations, but we must train ourselves to always be alert, drive defensively, and in this manner compensate for the other driver's lack of knowledge or so-called mistakes, if we hope to survive on our highways, Right or Wrong.

Lesson 1 - Introduction to the Course

OBJECTIVES

1. To become acquainted with members of the class
2. To provide a description of the course
3. To point out the value of this unit in the training of a technician

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Introduction	* Print the name of the course and your name on the chalkboard, and give a brief description of your experience.
II. Purpose of Course	* Explain that the course is being given primarily for the upgrading of

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Department of Transportation technicians in the design office and in the field including: 1. Engineer technician 2. Surveyor's assistant 3. Inspector on construction 4. Design tracers
III. Introduction of Class Members	* Have each student introduce himself to the class, volunteering such information as his occupation and where employed.
IV. Required Student Equipment	
A. Textbook	* Write on the chalkboard the name of the basic textbook for the course, Ref. A. * Point out the advisability of owning a text. * Ask the students to sign a sheet for a group order.
B. Looseleaf notebook	* Suggest the advantages of keeping a looseleaf notebook for the recording of class notes and important job information.
C. Engineer's scale	* Stress the importance of owning an engineer's scale.
D. Instruments and equipment	* List on the chalkboard the equipment needed for this course: 1. Drawing pencils, 4H, 2H, and B 2. Penholder 3. Crow quill penholder 4. Crow quill penpoint 5. Tank penpoint (B-6) 6. Hunt penpoints, Nos. 22, 30, and 38 7. Drawing set 8. Drawing board and T-square 9. Drawing paper 10. Black india ink 11. Erasing shield and ruby eraser 12. Sharpening stone

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
E. Maps	* Order rural and urban 7½ min. U.S.G.S. maps of your area. Each student should buy both maps.
V. Course Prerequisites	* State that the students must have some knowledge of algebra and geometry, which is given in Unit I of the Highway Series.
VI. Course Description	* Indicate that this course covers many facets of drawing that are only indirectly related to highway work.
A. Title and brief resume of each lesson	* Explain briefly the subject material that is covered in each of the 14 lessons of this unit.
1. Introduction to the course	* Indicate that Lesson 1 gives a brief outline of the material covered in the course.
2. Drawing equipment	* Mention that Lesson 2 covers all the necessary equipment used in ordinary engineering drawing.
3. Use of drawing equipment	* State that Lessons 3 and 4 describe the proper nomenclature, manipulation, and adjustment of drawing equipment.
4. Topographic maps	* Emphasize that Lesson 5 presents a specialized type of drawing that records to scale the topographic features of a portion of the earth's surface.
5. Topographic symbols	* Indicate that Lesson 6 covers the conventional symbols used on topographic maps to convey a variety of information.
6. Abbreviations, lettering, and inking	* Explain that Lesson 7 presents the techniques that will make a topographic map more meaningful.
7. Techniques of reproducing drawings	* Point out that Lesson 8 presents the fundamentals required to produce an ink tracing. Explain that many copies of a drawing may be required and that the student should be familiar with the different methods of duplicating drawings.

Lesson 2 - Drawing Equipment

OBJECTIVES

1. To introduce the language of drawing
2. To provide the basic information on the drawing equipment necesary for engineering drawing

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Engineering Drawing	* State that engineering drawing is a graphic language used by engineers to describe the shape, size, condition, and detail of structures, mechanisms, and land surfaces. (Ref. A, pp. 1-2; Ref. B, pp. 1-2)†
A. Purpose	* Explain that drawing is a method an engineer uses to record and convey his instructions to others.
B. Importance to the technician	* Note that engineering drawing affords an insight into the engineer's method of attacking engineering problems. (Ref. B, p. 3)
II. Drawing Equipment	* Explain the necessity of all technicians and students of engineering drawing owning at least a minimum amount of equipment.
A. Drawing instrument set	* Mention that there are many expensive and elaborate sets available, but only certain basic tools are required. (Ref. B, pp. 27-29)
1. Compass	* Show examples of the three main designs of the compass. (Ref. A, pp. 23-25)
a. Construction	* Explain that the joints of the compass are pivoted to maintain a constant, regulated pressure on the points.

†Reference citations are shown on page 1.

22049

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
b. Combination	* Illustrate the double use of the compass which allows insertion of either the pen leg or an extension leg.
c. Adjustments	* Show how a compass may be tested for alinement by checking the point of the needle against the closed nibs. (Ref. A, p. 36)
2. Dividers	* Explain the difference between the compass and the dividers.
	* Illustrate how the dividers are used to separate a line into equal parts.
a. Construction	* Exhibit the difference between the plain divider and the hairspring divider. (Ref. A, p. 22)
3. Bow instruments	* Describe and exhibit the bow divider, bow pencil, and bow pen. (Ref. A, p. 23)
a. Construction	* Illustrate a bow compass of the continuous type and one of the loop-spring type, with either a side or center adjusting screw. (Ref. B, p. 29)
b. Preference	* Point out that the loop-spring type is stronger and provides more uniform pressure.
c. Adjustments	* Explain that the side adjusting screw can be turned by holding the legs together, which takes the pressure off the nut and minimizes the wear on the thread, but the center screw provides a faster adjustment because of its double action.
4. Ruling pen	* Exhibit the common ruling pen available. (Ref. A, p. 26)
a. Construction	* Show that the steel blades are formed from one solid piece of high-grade steel.

13. Aerial photography the digital comput

* Note that Lesson 9 discusses the problem of distortion that results when a portion of the earth's surface is projected onto a flat surface. The lesson also covers the various projections that have been developed to secure as accurate a map as possible by reducing distortion to a minimum.

* Indicate that Lesson 10 explains in detail the information found on U.S. Geological Survey Maps. The lesson also includes instruction on reading and interpreting of these maps.

* Mention that Lesson 11 gives the rules used to secure and plot information obtained in the field.

* Explain that the lesson also includes the opportunity to plot topography from a highway survey.

ons) * State that Lesson 12 discusses the methods of securing a true picture of a land area by placing differences in elevation on a map.

* Add that the lesson also includes the plotting and studying of profiles and cross-sections.

* Emphasize that Lesson 13 covers the method used by the design staff to indicate to the contractor the way the highway is to be built.

* Note also that the lesson includes highway plan composition and interpretation.

and er * Point out that Lesson 14 covers the recent advances made in the field of aerial photography with respect to highway design.

* Mention that the lesson also includes the rudiments of photogrammetrics and its relationship to the digital computer.

TO THE INSTRUCTOR

Highway Drawing is the second in a series of nine courses which provide fundamental information to prepare your students for advanced work in highway planning, design, construction, and maintenance. Follow the content as closely as possible. Keep in mind that topics other than those in this unit are covered in other units of the Highway Technician Program. The units are planned to be given in numerical order as adult (or continuing) education courses.

In general, lessons in each of the units are planned for a session of 2 hours and 40 minutes. You may adjust this period to fit the class level, time schedule, and classroom situation. This course contains 14 lessons.

Plan each lesson before you present it to your class. You will need to plan classwork, discussion, and review. The left-hand column of each lesson contains suggested topics to be covered. The right-hand column gives accepted techniques, methods, and tips, as well as related information which should help you achieve effective teaching. Also this column shows page references for selected books for which the complete citations and symbols are given on page 1. Specific assignments are given at the end of each lesson. You should preview each lesson and arrange for needed visual aids and reference material in advance of the class.

Use the chalkboard, overhead projector, charts, diagrams, and other visual aids to clarify the material being presented. Duplicate for student use any important reference material. Give typical job situations as illustrations whenever possible.

Give a summary of key points at the end of each lesson. Also refer to past and future lessons and remind the students of needed references and other materials for the next lesson. Emphasize to the students that answers to the questions for each lesson provide a good summary of the important points.

A final examination is provided at the end of this Guide. The questions are derived from the basic material given in the lessons and the difficulty of each type is in proportion to the importance placed on any particular phase. The questions are in the form of multiple choice, true-false, completion, and matching and must be completed in 1 hour. The correct answers given in each case are for the instructor only, and the spaces are to be left blank in presenting the questions to the students.

As an instructor uses this course guide, he may have ideas for improving its content. Any suggestions he wishes to make should be addressed to the New York State Education Department, Bureau of Continuing Education Curriculum Development, Albany, New York 12224.

22042

NATIONAL BUREAU OF STA

N TEST CHART

ANDARDS-1963-A

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Point out that a thumbscrew is used to regulate the distance between the nibs.
b. Maintenance	* Note the different types of devices used to open the blades for cleaning.
5. Drawing board	* Exhibit the type of drawing board in common use.
a. Construction	* Explain that a drawing board is made of soft textured, straight-grained, thoroughly seasoned wood. It is from 3/4 to 1 in. thick, with the end pieces tongue and grooved to the main section. (Ref. A, p. 18)
	* Mention that the top surface of the drawing board must be smooth and true and that both working edges must be perfectly straight.
b. Sizes	* Point out that drawing boards are available from 12 x 17 in. to 60 x 120 in.
	* State that the size of board selected depends on the type of work that will be done.
6. T-square	* Exhibit a T-square and explain its construction. (Ref. A, p. 30)
a. Construction	* Explain that a T-square usually consists of a head of ebonized hardwood and a maple blade lined with transparent plastic so that the lines may be seen through the edge.
b. Types	* State that some heads are double and adjustable but that the working edges are the upper edge of the blade and the inside edge of the head.
	* Compare the T-square with the parallel rule attachment, mentioning the advantage of the permanent alinement of the latter.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
7. Triangles	* Exhibit a 45° and a 30°-60° triangle. Also show the class an adjustable triangle. (Ref. A, p. 20; Ref. B, p. 37)
a. Construction	* Mention that triangles may be made of various materials but that transparent, hard plastic is preferred. * State that the edges of the triangle must be perfectly straight and the angles true.
b. Sizes	* Point out that triangles are made in many sizes ranging from 2 to 36 in. and they should be a minimum of .060 in. thick.
8. Scales	* Display the four types of scales and explain the differences in graduations of the mechanical engineer's scale, the civil engineer's scale, the architect's scale, and the metric scale. (Ref. A, pp. 21-22; Ref. B, pp. 40-45) * Demonstrate the shapes of scales that are available and explain that thoroughly seasoned boxwood is used for their construction.
9. Curves	* Exhibit a variety of irregular or noncircular curves, which are commonly called french curves, and state that their edges are composed of combinations of different mathematical curves. (Ref. A, p. 22) * Point out that the best curve is made from a transparent plastic so that the work underneath is visible. * Mention that there are many designs and shapes on the market but that only a few curves are required to adequately cover most situations. * Show the class a series of circular curves which are definitely portions of circles.

22052

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
10. Pencils	* Note that a high-quality pencil has uniform lead and straight-grained wood. (Ref. A, p. 19; Ref. B, pp. 33-34) * Explain the system used by manufacturers to grade pencils according to their degree of hardness: 1. Design and layout work—9H, 8H, 7H, and 6H (very hard) 2. Centerlines, dimension lines—5H and 4H (medium hard) 3. Ordinary detail and line work—3H and 2H (medium) 4. Lettering—H and F (medium soft) 5. Sketching—HB, B, 2B, 3B, 4B, 5B, and 6B (soft) * Point out that the hardness of the paper must be considered when selecting the proper grade of pencil. * Display the automatic pencil which utilizes any one of the 17 hardnesses of lead.
11. Pencil pointers	* Show the sandpaper pad and the flat file and how they are used to sharpen a pencil or lead. * Display also an automatic pencil or lead pointer. (Ref. A, p. 20)
12. Erasers	* Exhibit the ruby pencil eraser and explain that only this should be used to erase both pencil and ink lines from paper or cloth, since it does not break into the fibers of the material. (Ref. A, p. 20) * Explain that the artgum or soft-rubber eraser is used to clean off smears, smudges, and fingermarks from the paper. * Exhibit an electric erasing machine and show the different types of erasers used with it.

22053

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
13. Erasing shield	* Display the different erasing shields available. * Explain that they are made from a very thin sheet of highly tempered spring steel and contain many odd-sized openings. (Ref. A, p. 20)
14. Drawing ink	* Point out that drawing ink (india ink) should be waterproof, free-flowing, and quick-drying. (Ref. A, p. 20) * Mention that it must not contain any chemicals which will corrode instruments, nor any ingredients which will separate out of solution.
15. Penpoints	* Show several types of penpoints and mention that individual experience is the best guide in the selection of a penpoint. * Explain that a good penpoint is one that has enough resistance to normal pressure to permit the drawing of curved and straight strokes of uniform width. (Ref. A, p. 93; Ref. B, pp. 7-8) * Mention that several penpoints are tank pens which are graded from a thin line to a wide line. * Explain that the Rapidograph type of pen is an india ink fountain pen and emphasize the necessity of keeping it thoroughly clean.
16. Protractor	* Display a semicircular or circular protractor and show how it is used to measure an angle. (Ref. B, p. 30)
17. Drawing paper	* Exhibit the most common type of drawing paper (buff-colored manila paper) and show how the slightly grained surface readily takes pencil work and repeated erasures. (Ref. A, p. 18)

22054

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Placement	* Indicate that the right-handed draftsman places the triangle on the right of the line being drawn. A left-handed draftsman places the triangle on the left of the line being drawn.
2. Control	* Mention that the T-square blade is held with the palm and thumb of the left hand while the triangle is held and adjusted by the fingers of the left hand.
3. Accuracy	* Explain that a line should never be drawn to the extreme corner of the triangle.
4. Vertical lines	* Indicate that vertical lines are drawn upward along the vertical leg of the triangle. The horizontal leg is supported and guided by the T-square blade. * Ask the students to draw lines perpendicular to the horizontal lines already drawn on their sheet.
5. Inclined lines	* Mention that inclined lines of certain definite angles may be drawn by using the 30°-60° and the 45° triangles. (Ref. B, pp. 37-41)
a. To horizontal lines	* Demonstrate how a line that makes a 15° angle or any multiple of 15° with the horizontal line may be drawn. (Ref. A, p. 17) * Have the students draw lines at angles of 15° with a basic horizontal line.
b. To oblique lines	* Show how a line may be drawn at a 15° multiple with any oblique line. * Have the students draw lines at angles of 15°, 30°, 45°, 60°, and 75° with any random oblique line.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
6. Parallel lines	* Mention that two triangles in combination will enable one to draw a line parallel to a given line. (Ref. A, p. 32) * Ask the class to draw a straight line at random and then to draw lines parallel to it.
7. Perpendicular lines	* Show how a line may be drawn perpendicular to another by either of two methods: 1. Sliding triangle 2. Revolving triangle. (Ref. A, p. 32) * Ask the class to draw a line perpendicular to some of the lines on their paper but not to include the horizontal lines.
E. Scales	* Explain that in any drawing or layout the relative position of a line must be found by scaling. (Ref. A, pp. 32-35)
1. Purpose	* State that not all objects can be drawn full size because of space limitations. (Ref. B, p. 42) * Mention that while some objects may be drawn larger than actual size, most objects must be reduced. * Explain that the first reduction would be half-size or 1/2 in. on paper = 1 in. of object and that 1/4 size is 1/4 in. on paper = 1 in. of object. (Ref. A, p. 33) * Note that when working with a given scale, the work must be thought of and spoken of in its full-scale dimensions and not in its reduced size.
2. Architect's scale	* Emphasize that architects use the quarter scale (not the quarter size), which is 1/4 in. = 1 ft.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Engineer's scale	* Stress that in highway work the engineer's scale is used. (Ref. A, p. 33)
a. Divisions	* Explain that each inch is divided into 10, 20, 30, 40, 50, and 60 parts or divisions. * State that in drawing a plan on a 50-ft. scale, 1 in. on paper is equal to 50 ft. on the ground.
4. Mechanics of scaling	* Show how the scale is alined and how points are marked off. * Emphasize the importance of placing eyes directly over the scale. (Ref. A, p. 33; Ref. B, p. 45) * Direct the students to mark off lines using the different scales.

QUESTIONS FOR REVIEW

1. Why should a pencil be rotated when drawing a line?
2. Is it possible to draw a line inclined at 15° from the horizontal blade of a T-square if only a 30°-60° triangle is used with a 45° triangle?
3. When using a triangle on a T-square, in which direction is a vertical line drawn?
4. What is the major difference between the engineer's scale and the architect's scale?

ASSIGNMENT

1. Study pages 35-44 in Ref. A.
2. Ask the class to draw five circles on a sheet of drawing paper and, using the T-square and triangles, divide each circle into 4, 6, 8, 12, and 24 parts.

QUESTIONS FOR REVIEW

1. Describe briefly what is meant by engineering drawing.

2. What type of bow instrument construction provides the more uniform pressure?

3. What would be the most important requirement of the wood used to make an engineer's scale?

4. When would you use a 2B pencil? A 5H pencil?

5. What is the most important attribute of india ink?

6. How does water affect tracing cloth?

7. Is a pair of proportionate dividers fixed for one given scale?

ASSIGNMENT

1. Study pages 28-35 in Ref. A.

INSTRUCTOR'S NOTES

22056

Lesson 3 - Use of Drawing Equipment

OBJECTIVE

To demonstrate the proper techniques of handling drawing equipment

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Technique Requirements for Drawing	* Explain that a good drawing technique is essential and this is a matter of habit. (Ref. A, p. 28)†
A. Accuracy and speed	* Mention that the goal of the technician is to draw rapidly and accurately. A poor drawing takes as much time to do as a good one.
II. Preparation for Drawing	
A. Light and table	* Point out that the light should come from the left when working on a drawing and that the table should be slightly inclined at about 1 to 8 slope. (Ref. A, p. 28)
B. Neatness	* Mention that the table, board, and equipment should be wiped off with a cloth before starting to work.
III. Basic Equipment and Procedures for Drawing	
A. T-square	* State that the T-square is used for drawing horizontal lines and for guiding triangles. (Ref. A, p. 30; Ref. B, p. 37)
1. Placement	* Show that the T-square is used with the head held firmly against the left edge of the board.
2. Control	* Ask the students to slide the T-square with their left hand until they have full control.

†Reference citations are shown on page 1.

22057

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Explain that for a closer positioning the thumb can be placed on the top of the head, while the fingers of the same hand press against the bottom of the board. Or the fingers can remain on top of the head with the thumb on the board. Indicate that the latter method is preferred.
3. Left-handed students	* Indicate that all operations are reversed when the draftsman is left-handed.
	* Point out that the T-square is used on the right edge of the board and that horizontal lines are drawn from right to left.
	* Emphasize that the light should come from the right in the case of a left-handed person. (Ref. A, p. 32)
B. Drawing paper	* Exhibit the heavy buff-colored manila drawing paper used in class.
1. Position on board	* State that the paper is placed on the board close to the working edge and several inches from the bottom of the drawing board. (Ref. A, p. 29; Ref. B, p. 36)
	* Ask each student to place a sheet of paper on his board, squaring the top of the paper with the T-square.
2. Holding on board	* Explain that either tape or tacks can be used to hold the paper on the board but that tacks are obstacles. Point out that tape becomes sticky in hot weather.
C. Pencil	* Point out that the first work in drawing consists of simple pencil lines.
1. Selection	* Indicate that the pencil selected should neither smudge nor cut grooves in the paper.

22058

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* State that the surface of the paper being used and the quality of line desired also influence the selection of a pencil. (Ref. A, pp. 28-29)
	* Note that a 5H or 6H pencil is used for layout work and construction lines and a 2H, 3H, or 4H pencil is used for a finished drawing. (Ref. B, pp. 32-34)
2. Sharpening	* Demonstrate how to cut away the wood from the unlettered end of a pencil with a penknife, making a long conical point.
	* Show how to point a pencil with the sandpaper file.
3. Control	* Explain that the pencil is held firmly but not tightly and, while applying a constant pressure, is rotated as a line is drawn.
	* Indicate that the pencil is inclined slightly in the direction the line is being drawn, and slightly away from the body so that the point is close to the blade of the T-square. (Ref. A, p. 30; Ref. B, pp. 35-36)
	* Explain that the pencil hand glides along the blade of the T-square on the little finger.
	* Ask the students to place pencil points on the paper and then to draw horizontal lines through these points, using the T-square.
	* Indicate that lines are drawn from left to right.
D. Triangles	* Emphasize that there are certain procedures to follow when using triangles. (Ref. A, pp. 30-33)

22059

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Nib sharpening	* Illustrate how pen nibs are sharpened on a hard Arkansas knife piece. (Ref. A, p. 38; Ref. B, pp. 52-53) * Show how burrs are removed by opening the blades completely and rubbing the inside surface of each blade flat on the stone. * Explain that a hairline can be drawn easily when a ruling pen is properly sharpened.
C. Control	* Indicate that the pen is held by the fingertips with thumb and second finger on the nibs and the handle resting on the forefinger. The tips of the third and fourth fingers rest on and glide along the straightedge. (Ref. A, pp. 39-40; Ref. B, pp. 49-50) * Note that the pen is held against the straightedge with the blades parallel to it. The screw is always facing the outside. * Mention that the handle of the pen is inclined to the right and always in a plane passing through the line and perpendicular to the paper. * Point out that the pen is guided by the upper edge of the straightedge. * Explain that a line is drawn with an even arm movement. (Ref. B, pp. 49-50) * Mention that as the end of a line is approached, the guiding fingers are stopped and without interrupting the motion of the pen the line is abruptly finished with a finger movement. * Note that the pen pressure is light, in general, but it does vary with the type of paper and the sharpness of the pen.

VT 011 919
Suggested Curriculum in Office Occupations.

Gila River Career Center, Ariz.
Central Arizona Coll.
Arizona State Dept. of Vocational Education, Phoenix.
Four Corners Regional Commission, Ariz.
MF AVAILABLE IN VT-ERIC SET.
PUB DATE - ND 64p.

DESCRIPTORS - *CURRICULUM GUIDES; *OFFICE OCCUPATIONS EDUCATION; *FILE CLERKS; *STENOGRAPHERS; *TYPISTS; OFFICE OCCUPATIONS; VOCATIONAL EDUCATION

ABSTRACT - Intended to aid in preparing students for entry and advancement in office occupations, this program provides detailed outlines for the four major office occupations of receptionist, file clerk, clerk-typist, and stenographer. Contents give general information on the program, including a flow chart of student progression through all phases of the program, followed by the course outlines, which are broken down into separate instructional units giving course description, course objectives, suggested hours, and teaching aids and suggestions. The course is designed to provide terminal points within the total program in order to provide students with some saleable skills regardless of whether or not the entire program is completed. (AW)

VT 011 919

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* State that when ink will not flow in the pen the problem can sometimes be corrected by touching or pinching the blades.
	* Suggest that dried ink should be wiped away and a fresh supply added.
D. Inking rules	* Note that ink lines must be centered over pencil lines.
	* Tell the students that when they are inking circles, arcs, and straight lines that touch they should ink the circles and arcs first and keep the points of contact equal to the width of one line. (Ref. A, p. 40)
V. French Curve	* Describe how the french curve is used as a template for non-circular curves. (Ref. A, pp. 42-43; Ref. B, p. 48)
	* Show that a french curve is applied so that at least three points are on the edge of the curve.
	* Mention that to avoid cusps or humps, each line drawn should start and stop short of the first and last points being fitted.
A. Practice	* Have the class place a series of points and use the french curve to connect them, first in pencil, and then in ink.
	* Note that ink work with the french curve is the best practice available.
VI. Protractor	* Indicate that a protractor is divided into degrees and parts of a degree. (Ref. A, p. 646)
	* Show how a protractor is used to measure and to lay out an angle.
A. Practice	* Have the class draw specific angles with a protractor.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
VII. Erasers	* Explain that a ruby eraser removes pencil lines satisfactorily and removes ink lines effectively without damaging the paper. (Ref. A, p. 20) * Mention that an erasing shield helps to obtain clean erasures. * Note that when a line has made a groove in the paper the spot should be rubbed with a burnisher or the back of the thumbnail. * Explain that a gum eraser is used to remove soft pencil lines and smudges. * Advise the class not to use an ink eraser since too much of the fiber of the paper is removed. * Caution the students not to use a knife or razor blade for the removal of ink lines. * Point out that proper erasing procedure must be learned. (Ref. A, pp. 20, 43-44; Ref. B, p. 48)
VIII. Standard Line Symbols	* Explain that symbolic lines of different widths are used to make technical drawings. All the lines needed may properly be called an "alphabet of lines." (Ref. A, pp. 41-42) * Draw on the chalkboard the symbols for the following: 1. Visible outline 2. Hidden outline 3. Centerline 4. Dimension line 5. Extension line 6. Repeat line 7. Short break 8. Long break

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Line widths	* Inform the class that there are three widths of lines: 1. Thick—used for visible outline, cutting plane, and short break lines 2. Medium—used for hidden outline 3. Thin—used for centerline, dimension, extension, repeat, long break, and section lines (Ref. A, p. 42; Ref. B, pp. 54-55) * Emphasize that each line size should be readily distinguishable. * Explain that construction lines are drawn very fine so as to be unnoticeable on the completed drawing.
B. Line width recommended by Department	* State that architecture and engineering have their own method of line identity. * Distribute to each student a print of "Standard Symbols and Abbreviations." (Ref. E) * Point out that the line widths suggested by the State Department of Transportation for use on highway design plans are listed on the Standard Symbols Sheet. This information is shown in Tables 1 and 2 on page 27.
C. Practice	* Request the class to practice the drawing of pencil lines, checking particularly the width of lines, texture, and uniformity. * Ask the class to ink the pencil lines and then to analyze their errors or problems. (Ref. A, p. 42)

TABLE 1 SUGGESTED LINE WIDTHS PLAN	
Feature	**Symbol**
EXISTING TOPO. (PRINTING)	NO. 00 NO. 0
NEW CONST. (PRINTING)	NO. 3 NO. 1
LIMITS OF CONST.	NO. 1
NEW R.O.W.	NO. 2
℄ OF IMPROVEMENT	NO. 3

Table 2 SUGGESTED LINE WIDTHS PROFILE	
Feature	**Symbol**
DATUM LINE	NO. 2
VERT. LINES ℄	NO. 00
EXIST. GRADE LINE	NO. 0
NEW GRADE LINE	NO. 3
FLAGS (PRINTING) NEW EXISTING	 NO. 1 NO. 0

Note: All line thicknesses refer to those made by Koh-I-Noor Rapidograph pen. Adjust ruling pens to comparable widths. The size of symbol varies according to the scale of the drawing.

QUESTIONS FOR REVIEW

1. How much of the compass lead should be sharpened and beveled?

2. What is the largest circle which can be drawn with a compass without utilizing the lengthening bar?

3. Explain how the compass is adjusted to fit a radius mark.

4. When is the bow compass used?

5. Describe the problems encountered when the blades of a ruling pen are either too pointed or too rounded.

6. Explain the position of the fingers on the ruling pen when drawing a straight line.

7. What is the alphabet of lines?

8. Is it possible to erase india ink from tracing cloth by using only a ruby eraser?

ASSIGNMENT

1. Study pages 597-605 in Ref. A.

2. Study the "Page of Cautions" listed on page 44 of Ref. A.

3. Pencil and ink the designs in Problems 2.1.3, 2.1.7, 2.2.4, 2.2.5, and 2.3.3 on pages 45-46 in Ref. A.

INSTRUCTOR'S NOTES

22071

Lesson 5 - Topographic Maps

OBJECTIVE

To provide the basic information about recording to scale the topographic features found on a given portion of the earth's surface

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Purpose	* State that the purpose of a topographic map is to convey quickly to the trained person a mass of information. Conventional symbols, authorized abbreviations, lettering, and distinctive colors are used to achieve this result. (Ref. C, p. 1)†
	* Point out that a topographic map is a combination of both freehand and mechanical draftsmanship.
II. Type	* Note that a topographic map corresponds to a plan view in mechanical drawing.
III. Classes of Topographic Maps	* State that in general all topographic maps fall into four classes, grouped according to use (Ref. A, pp. 597-598; Ref. C, pp. 2-4): 1. Geographic maps 2. Cadastral or city maps 3. General topographic maps 4. Engineering or working maps
A. Geographic maps	* Define the geographic map as one which covers a large area and shows only the most prominent relief, culture, and hydrographic features.

†Reference citations shown on page 1.

22072

Lesson 4 - Use of Drawing Equipment

OBJECTIVE

To demonstrate the proper techniques of handling drawing equipment

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Dividers	* State that the dividers are used for transferring measurements and for dividing lines into any number of equal parts. (Ref. A, pp. 35-36; Ref. B, p. 46)†
A. Control	* Show how the dividers are held in one hand.
B. Trial method of line division	* Explain how a line may be divided into equal parts by estimation and retrial. (Ref. A, p. 36)
C. Practice	* Ask the class to divide a straight line into certain divisions.
	* Have the student divide the circumference of a circle into a certain number of divisions.
II. Compass	* Point out that the compass is used primarily for drawing circles and arcs. (Ref. A, pp. 36-38)
A. Compass lead	* Mention that the type of work determines the type of compass lead to use but in general a hard lead gives satisfactory results.
	* Explain that the compass lead must be sharpened to a flat bevel about 1/2 in. long. (Ref. B, pp. 45-46)

†Reference citations are shown on page 1.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Needle adjustment	* Show that the needle should extend 3/8 in. beyond its sleeve and that it should be just slightly longer than the compass lead.
C. Use	* Emphasize that in drawing a circle two intersecting lines at right angles must be drawn and a radius marked off. * Show how the pivot point is guided accurately into position at the center, adjusting the pencil point to the radius mark. * Indicate that the handle is rotated between thumb and finger, as the circle is drawn in a clockwise direction. * Note that the compass is inclined slightly in the direction of the line. (Ref. A, p. 37) * State that for circles over 2 in. in radius the pivet legs have to be bent so that both nibs of the pen will touch the paper at the same time. * Explain that the lengthening bar is used for circles over 5 in. in radius. * Note that when concentric circles are drawn the smallest one is made first as the center hole becomes worn with use. (Ref. A, p. 38)
D. Practice	* Ask the students to draw different sized circles, following all of the above instructions.
E. Pen leg	* Show how the pencil leg is replaced with the pen leg. * Demonstrate how the pen is filled with ink. * Caution the class not to use more than 1/2 in. of ink in the pen. (Ref. A. p. 39)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Remind the students that the needle should extend slightly beyond the pen.
F. Practice	* Ask the students to fill their compass pens and ink the pencil circles already drawn.
III. Bow Instruments	* State that the bow pen and the bow pencil are used to draw small circles having a radius of 1 in. or less. (Ref. B, p. 47)
	* Explain that bow instruments are used like the larger type dividers. Note that it is possible to obtain greater accuracy with the locked-in bow dividers.
A. Adjustments	* Demonstrate how small changes are made with the fingers that hold the instrument.
	* Mention that large changes for the side screw type are made only after the pressure is taken off the threads by closing the legs with the left hand.
B. Practice	* Instruct the class to draw a series of small circles with both the pencil and pen bow instruments.
IV. Ruling Pen	* Point out that the ruling pen is used to draw straight lines and flat curves. (Ref. A, pp. 38-39)
A. Nib shape	* Sketch on the chalkboard the proper shape of the ruling pen nibs and show how they become pointed and rounded by use.
	* Emphasize that pointed nibs will not allow the ink to flow freely and rounded nibs will cause the ink to flow too freely.
	* Explain how to use the reflection method to check for dullness of the nibs.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Explain that the scales for geographic maps usually vary from 1:1,000,000 to 1:62,500. This is equal to 1 in. = 15 mi. to 1 in. = 1 mi. The numerator, usually 1, represents map distance and the denominator, a large number, represents the actual distance with both being expressed in the same unit.
B. Cadastral maps	* Mention that cadastral maps are made as a control in the development and growth of a large city or a suburban district.
	* Indicate that the scale for cadastral maps usually varies from 1 in. = 1,000 ft. to 1 in. = 200 ft.
C. General topographic maps	* Point out that general topographic maps are especially made for a given project such as a very large industrial expansion, a hydroelectric project, drainage development, or flood control.
	* Indicate that the scale for general topographic maps usually varies from 1:62,500 to 1:6,000 or 1 in. = 1 mi. to 1 in. = 500 ft.
	* Note that these maps are not as accurate as the cadastral maps.
D. Engineering maps	* Explain that engineering maps are the ones we are most concerned with as they cover the preliminary planning and construction plans for any engineering project.
	* Point out that the scale of engineering maps usually varies from 1:2,400 to 1:240 or 1 in. = 200 ft. to 1 in. = 20 ft.
	* Note that the amount and nature of the information shown varies according to the final purpose and use of these maps.

adapted from
previously developed
material by

Gila River Career Center in cooperation
with Central Arizona College, the Arizona
State Department of Vocational Education,
and the Four Corners Regional Commission

VT011919

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
IV. Scale	* Define the scale of a map as the constant ratio of dimensions of objects and distances on the map to the corresponding actual dimensions and distances on the ground. (Ref. C, pp. 18-20)
	* Explain that the scale will apply only to horizontal distances since everything on a topographic map is shown in a plan view.
	* Note that vertical distances are shown to scale by means of the contour interval.
A. Scale control	* Point out that only controlling distances and the most important objects are shown to scale. General background details, consisting of symbols for forests, trees, meadows, etc., are not shown to an exact scale.
B. Scale choice	* Explain that the choice of scale depends on the purpose for which the map is to be used. In general a 50-ft. scale is used on the rural highway and a 20-ft. scale for city arterial work.
	* Indicate that the equation for a scale is $1/F = S/L$. (Ref. C, pp. 20-23; Ref. D, p. 639)
V. Content	* State that the information shown on a topographic map is divided into four major classifications (Ref. A, p. 606; Ref. C, pp. 1-2): 1. Culture or manmade works 2. Relief or contours indicating differences in elevation 3. Hydrographic or water features 4. Vegetation
A. Culture	* Explain that culture embraces all the features built or constructed by man with the exception of canals and artificial cuts and fills, which fall into either hydrographic or relief

22074

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	features. Included in this classification are highways, railroads, towns, houses, fences, and property lines.
B. Relief	* Indicate that relief is shown by certain conventional symbols or by a combination of symbols and lettering. * Note that valleys, hills, plains, plateaus, and mountains are included in this classification. * Explain that variations in elevation of the earth's surface are indicated by contour lines.
C. Hydrography	* Define hydrographic features as those showing all information pertaining to water. They include oceans, seas, lakes, ponds, rivers, and creeks.
D. Vegetation	* Point out that vegetation includes all natural features such as forests, orchards, crops, and meadows.
VI. Contour	* Define a contour as a theoretical line of constant elevation on the ground. (Ref. D, pp. 631-633) * Explain the following points about contours: 1. Points of equal elevation are joined by a contour line. 2. Contours on the ground are represented by contours on the map. 3. The horizontal distance between contour lines is inversely proportional to the angle of the slope. 4. On uniform slopes the contour lines are spaced uniformly. 5. On plane surfaces the contour lines are straight and parallel to one another.

22075

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	6. Contour lines are perpendicular to lines of steepest slope. 7. All contour lines must close upon themselves either within or without the borders of the map. 8. The smallest closed contour line on a map indicates either a summit or a depression. 9. Contour lines cannot cross one another except in the case of a vertical cliff. 10. Contour lines bend toward the upgrade when crossing a stream or valley and toward the downgrade when crossing a ridge. (Ref. C, pp. 143-144)
A. Contour interval	* Define the contour interval as the vertical distance between contours. * State that the choice of interval depends on the horizontal scale and on the purpose of the map. * Indicate that the usual contour interval for ordinary work is 20 ft. and the 1-ft., 2-ft., and 5-ft. intervals are used on large scale maps.
VII. Construction	* Explain that topographic maps are constructed in three operations: 1. Plotting horizontal control 2. Plotting details including locations of known ground elevations 3. Drawing contour lines at a given interval (Ref. D, p. 633)
A. Plotting horizontal control	* Mention that a horizontal control provides the skeleton of the drawing. * Note that the protractor and tangent offset are two methods commonly used to plot horizontal control.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Describe briefly the procedure of establishing a reference line or base line on the ground, using a transit and tape (portion of the survey course).
	* Explain that this base line is then oriented from the north in some manner.
	* Indicate that this base line is positioned on the paper exactly as it exists on the ground and is then drawn to scale.
1. Protractor method	* Explain that in the protractor method the position on the paper of the first line is determined by estimation only and that its actual length is laid off by measurement. (Ref. C, pp. 91-93; Ref. D, pp. 446-447)
	* Mention that in a survey the second line is referenced off the first line (portion of survey course).
	* Show that the protractor is oriented at the forward point of the first line. The deflection angle of the next line is marked off and a line of indefinite length is drawn.
	* Explain that the actual distance is measured off on this line, which determines the point for the next step.
	* State that every line is lettered or stationed at each extremity.
	* Emphasize the need for accuracy to avoid errors which will affect the correctness of the entire project.
2. Tangent offset method	* Explain that the tangent offset method is similar to but more precise than the protractor method. (Ref. C, pp. 93-96; Ref. D, pp. 447-450)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Note that the position on the paper of the first line represents a plotted position and is drawn longer than required. The actual length is marked off and lettered.
	* Mention that this line is extended 10 in. and at the end a perpendicular is erected in the direction of the next part of the base line.
	* Explain that along this perpendicular is measured off a distance equal to 10 in. times the natural tangent of the deflection angle.
	* Show how a line is drawn from the end of the plotted line to the measured distance on the perpendicular line. Then the actual length is measured off and lettered. This becomes the starting point for the next step.
B. Plotting details	* Point out that plotting details is less refined than plotting horizontal control. (Ref. C, p. 103; Ref. D, pp. 466-468)
	* Emphasize the importance of plotting objects of definite size and shape with enough precision so that dimensions may be scaled off.
C. Constructing contour lines	
1. Ground point	* Explain that a point may be located by a right angle offset from a certain point or station on the base line or by an angular reading together with a distance from a base line.
	* Describe briefly that the methods used to find elevations in the field are: 1. Section method 2. Checkerboard method 3. Random spot method (Ref. D, pp. 634-638)

22078

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* State that a point of known elevation is called a ground point.
	* Point out that a ground point on a contour is called a contour point.
	* State that a map has vertical dimension when ground points have been obtained and plotted.
2. Contour interval	* Explain how to select a suitable contour interval.
3. Locating contour lines	* Describe the method of interpolation by which contour lines are drawn for a given set of elevations.
	* Show how to use the checkerboard system of available elevations for locating contours and sketch on the chalkboard a block of several squares with an elevation at every intersection. (Ref. D, p. 635)
a. By estimation	* Note that when a desired contour falls between two given elevations, its position is estimated by eye. (Ref. D, p. 635)
b. By computation	* State that when a desired contour falls between two given elevations, its position is determined mathematically. (Ref. D, pp. 635-636)
	* Indicate that two intersections of the checkerboard have elevations of 857.9 ft. and 862.8 ft. Note that there is a differential of 4.9 ft. between them.
	* Show how the 858, 860, and 862-ft. contours are placed by the following methods:
	1. Point out that the 858-ft. contour is .1 ft. above the known elevation of 857.9 ft. The 858-ft. contour is placed .1 of 4.9 (total difference in elevation) of the map distance between the two known elevations.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	2. Point out that the 860-ft. contour is 2.1 ft. above the known elevation of 857.9 ft. The 860-ft. contour is placed 2.1 of 4.9 (total difference in elevation) of the map distance between the two known elevations.
	3. Point out that the 862-ft. contour is 4.1 ft. above the known elevation of 857.9 ft. The 862-ft. contour is placed 4.1 of 4.9 (total difference in elevation) of the map distance between the two known elevations.
c. By graphics	* Demonstrate the method of graphic interpolation, using a piece of coordinate paper. (Ref. D, p. 636)
	* Mention that a rubberband graduated at equal intervals, similar to the coordinate paper, can also be stretched between two points to furnish an interpolation.
4. Drawing contour lines	* Explain that when drawing contour lines the procedures below should be followed:
	1. Use skill and judgment when placing contour lines so they may best represent the actual configuration of the ground.
	2. Draw contours as lines that are smooth and of uniform width.
	3. Draw every fourth or fifth contour as a heavier line. (Ref. C, p. 108; Ref. D, p. 634)

QUESTIONS FOR REVIEW

1. Name the four general classifications of information found on the ordinary topographic map.

2. What is a contour line?

22080

3. Describe the scale of a geographic map.
4. What is the scale ordinarily used for a cadastral map?
5. What is meant by the map scale?
6. Explain the equation of a scale.
7. Why must all contour lines eventually close upon themselves?
8. When do contour lines cross themselves?
9. What three operations are necessary to draw a topographic map?
10. Describe a contour point.
11. Name three methods of interpolating elevations.

ASSIGNMENT

1. Study pages 602-605 in Ref. A.
2. Distribute prints of a grid sheet consisting of 100 squares at a 20-ft. scale with elevations at each intersection. Restrict the elevations from 50 ft. to 70 ft. and ask the class to draw a contour map using a 1-ft. interval.

INSTRUCTOR'S NOTES

22081

Lesson 6 - Topographic Symbols

OBJECTIVE

To provide the information necessary to represent features on a topographic map by means of symbols

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Use of Symbols	* Indicate that the symbols used are standard and of a size that blends with the drawing. (Ref. A, pp. 606-610; Ref. C, p. 25)†
	* State that the symbols taught first are those used throughout the world.
	* Note that the Department of Transportation's Standard Symbol Sheet (distributed in Lesson 4) differs slightly in nomenclature, classification, and composition from other standard symbols. Department personnel are to use only the recommended symbols.
A. Legibility	* Point out that all the symbols are designed to be rapidly made, readily understood, and pleasing in appearance.
B. Plan view	* State that since the topographic map is a plan view, the symbol should resemble the plan view of the object it represents. Exceptions include telephone poles and crops. They are drawn in elevation for appearance and clarity.
C. Shading	* Explain that shading produces relief in a symbol. (Ref. C, p. 25)

†Reference citations are shown on page 1.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Mention that the source of light is assumed to be coming from above and to the left of the object at an angle of 45°.

* Note that the use of shading increases as the size of the map or the size of the scale increases.

D. Composition

* Indicate that the purpose of the map determines which symbols are emphasized. (Ref. C, p. 26)

E. Selection of pen

* State that the most successful work is done with a crow-quill pen or a reasonable facsimile. A limber, larger pen may be used when the draftsman has had some experience. (Ref. C, p. 26)

F. Construction rules

* Emphasize that the following rules should be observed when drawing symbols (Ref. C, p. 27):

1. Do not carry an excessive amount of ink in the pen.
2. Do not let the pen dry before refilling.
3. Use different pens for different colors.
4. Throw away any penpoint with a sprung nib.
5. Keep paper clean and avoid erasures.
6. Work in a relaxed position.

II. Classification of Symbols

* Indicate that commonly used symbols are classified under one of the following headings (Ref. C, p. 25)

1. Vegetation
2. Hydrography
3. Ground surface and character of soils
4. Subdivisions and surveying data
5. Works and structures
6. Railroads
7. Utilities
8. Standard cross-sections

CONTENT OUTLINE

III. Construction of Symbols

A. Vegetation

TEACHING POINTS AND TECHNIQUES

* Mention that some symbols are created by mechanical drafting while others are drawn freehand.

* Draw on the chalkboard the following symbols and have the class practice drawing them (Ref. C, pp. 29-35, 89):

1. Grass or cleared land
2. Corn
3. Deciduous trees
4. Oak trees
5. Orchard
6. Evergreens
7. Woods
8. Vineyard
9. Tobacco
10. Cultivated land
11. Wheat
12. Oats
13. Willows

* Analyze the symbols listed under No. 15 Trees and Brush on the Standard Symbols Sheet. This information is shown in Table 3 below.

* Explain that the amount of descriptive detail used on certain maps may not be required on highway plans.

Table 3 TREES AND BRUSH

Feature	Symbol	Remarks
WOODED AREA	W	IDENTIFY
BRUSH	B	IDENTIFY
TREE, SINGLE (DECIDUOUS)		IDENTIFY AS TO TYPE
TREE, SINGLE (CONIFEROUS)		IDENTIFY AS TO TYPE
ROW OF TREES		IDENTIFY
HEDGE ROW		
STUMP		IDENTIFY

Table 18 DAMS AND DIKES

DAM		
SPILLWAY		
DIKE	DIKE	USED WHEN CONTOURS ARE SHOWN
DIKE	DIKE	USED WHEN CONTOURS ARE NOT SHOWN
JETTY	JETTY	
PIER	PIER	

CONTENT OUTLINE

F. Railroads

TEACHING POINTS AND TECHNIQUES

* Indicate that modern clearance problems and grade elimination techniques require differentiation among the types of railroads.

* Draw on the chalkboard the following symbols and have the class identify as many as possible by analysis (Ref. C, pp. 54, 61):

1. Railroad
2. Electric railroad
3. Railroad in street
4. Railroad grade crossing
5. Grade crossing (railroad overhead)
6. Grade crossing (railroad under)
7. Railroad tunnel
8. Railroad bridge
9. Narrow gauge railroad
10. Trestle
11. Turntable
12. Signal tower
13. Railroad station

* Compare the above symbols with those listed under Number 11 Railroads on the Standard Symbols Sheet. This information is shown in Table 19 on page 53.

Table 19 RAILROADS

Feature	Symbol	Remarks
SINGLE TRACK		
MULTIPLE MAIN LINE TRACK		NUMBER OF TRACKS LABELED IF OVER TWO
ABANDONED TRACK		IDENTIFY
JUXTAPOSITION		
YARD OR SIDING		
TURN TABLE		
NARROW GAUGE SINGLE TRACK		
NARROW GAUGE MULTIPLE TRACK		NUMBER OF TRACKS LABELED IF OVER TWO
ABANDONED TRACK NARROW GAUGE		
HIGHWAY-RAILROAD CROSSING SIGN		
HIGHWAY-RAILROAD CROSSING GATE		
BRIDGE WARNING TELLTALE		
MILE POST		SHOW NUMBER

CONTENT OUTLINE

G. Utilities

TEACHING POINTS AND TECHNIQUES

* State that utilities can occupy the right-of-way of any highway, so they will appear on most maps concerning highway work.

* Draw on the chalkboard the following symbols (Ref. C, pp. 59, 61, 77):

1. Telephone or telegraph line
2. Electric power transmission line
3. Power distribution line

CONTENT OUTLINE

B. Hydrography

TEACHING POINTS AND TECHNIQUES

* Point out that only a few hydrographic symbols are used on highway plans. But stress that these symbols may be found on maps used to develop highway plans.

* Draw on the chalkboard the following hydrographic symbols and have the class practice drawing them (Ref. C, pp. 36-37, 46):

1. Pond
2. Small lake
3. Marsh or swamp
4. Brook
5. Small stream
6. River
7. Shore line
8. Current direction
9. Canal and lock

* Review the hydrographic symbols listed under No. 8 Water Locations on the Standard Symbols Sheet of the New York State Department of Transportation. This information is shown in table 4 on page 43.

* Review the hydrographic symbols used on U.S.G.S. topographic maps. (Ref. F, pp. 16-17)

C. Surface ground forms and character of soils

* Explain the two methods used to represent hills, mountains, and surface undulations. (Ref. C, p. 39)

1. By contours (preferred)
2. By some form of hill shading (not commonly used)

* Draw on the chalkboard the following symbols and have the class practice drawing them (Ref. C, pp. 35-36, 44):

1. Sand
2. Gravel
3. Mud
4. Rock

Table 4 WATER LOCATIONS

SEWER, STORM	— — St — —	INDICATE DIAMETER
MANHOLE	T	LETTER INDICATES TYPE

CONTENT OUTLINE

H. Standard cross-sections

TEACHING POINTS AND TECHNIQUES

* Explain that there is sometimes a need to describe the character of the material used in the symbol on a plan.

* Draw on the chalkboard the following symbols (Ref. C, p. 68):

1. Cinders
2. Crushed rock
3. Solid rock
4. Earth
5. Wood
6. Brick
7. Plain concrete
8. Reinforced concrete
9. Rubble
10. Concrete reinforced with mesh

* Mention that the Standard Symbols Sheet Number 3 Cross-Sections indicates some mixtures of commonly used materials. This information is shown in Table 22 on page 56.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Compare the above symbols with those listed under Numbers 9 Topography and 14 Cut and Fill Limits on the Standard Symbols Sheet. This information is shown in Tables 5 and 6 below.

Table 5 TOPOGRAPHY

Feature	Symbol	Remarks
CONTOURS		
DEPRESSION		
SAND DUNES		
MINE OR GRAVEL BANK		
BOULDERS		IDENTIFY
ROCK OUTCROP		IDENTIFY

Table 6 CUT AND FILL LIMITS

Feature	Symbol	Remarks
TOP OF CUT		IDENTIFY AT BOTH ENDS OF THE SHEET
BOTTOM OF FILL		IDENTIFY AT BOTH ENDS OF THE SHEET

D. Subdivisions and surveying data

* Emphasize that this classification embraces political and private subdivisions.

* Point out that much surveying data or field information must be symbolized on a set of plans.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Draw on the chalkboard the following symbols and have the class practice drawing them (Ref. C, p. 52):

1. National border
2. State line
3. County line
4. Town line
5. Village line
6. Reservation line
7. District line
8. City line
9. Cemetery line
10. Park line
11. Property line
12. Barbed wire fence
13. Smooth wire fence
14. Hedge fence
15. Rail fence
16. Snow fence
17. Worm fence
18. Stone fence
19. Stone monument
20. Iron monument
21. Iron pipe
22. Tree line

* Point out that the Department Standard Symbols Sheet Numbers 10 Surveying Data, 13 Boundaries, 19 Subsurface Explorations, and 20 Miscellaneous cover this category. This information is shown in Tables 7-10 on pages 45-47.

* Review the comparable symbols used on the U.S.G.S. maps. (Ref. F, pp. 16-17)

Table 7	MISCELLANEOUS

CONTENT OUTLINE

E. Works and structures

TEACHING POINTS AND TECHNIQUES

* Mention that only the most common symbols in this classification will be covered in this lesson.

* Draw on the chalkboard the following symbols and have the class practice drawing them (Ref. C, pp. 53, 54, 57, 77, 80):

1. Foundation
2. Mine and quarry
3. Tank
4. Cemetery
5. School
6. Church
7. Hospital
8. Highway
9. Trail
10. Dam
11. Ditch
12. Abandoned canal
13. Aqueduct

F. Railroads

TEACHING POINTS AND TECHNIQUES

* Indicate that modern clearance problems and grade elimination techniques require differentiation among the types of railroads.

* Draw on the chalkboard the following symbols and have the class identify as many as possible by analysis (Ref. C, pp. 54, 61):

1. Railroad
2. Electric railroad
3. Railroad in street
4. Railroad grade crossing
5. Grade crossing (railroad overhead)
6. Grade crossing (railroad under)
7. Railroad tunnel
8. Railroad bridge
9. Narrow gauge railroad
10. Trestle
11. Turntable
12. Signal tower
13. Railroad station

* Compare the above symbols with those listed under Number 11 Railroads on the Standard Symbols Sheet. This information is shown in Table 19 on page 53.

QUESTIONS FOR REVIEW

1. In shading a symbol, from what direction is the light assumed to be coming?

2. What type of pen is most successfully used in the drawing of symbols?

3. What are the different classifications of symbols in common use?

4. Why are symbols used on a topographic map?

ASSIGNMENT

1. Study pages 83-93 and 606-610 in Ref. A.

2. Complete problem 4.1.8 on page 94 in Ref. A.

3. Ask the students to ink, on one sheet of drawing paper, any 50 symbols of the standard sheet. Emphasize that the name of each feature is not to be placed on the drawing. Point out that these drawings will be exchanged with another student for feature identification.

Lesson 7 - Abbreviations, Lettering, and Inking

OBJECTIVE

To provide the techniques that will make a topographic map more meaningful

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Abbreviations	* State that abbreviations are used in order to conserve space and to expedite the drawing of a topographic map.
A. Standards	* Emphasize that all of the abbreviations used are authorized and can be recognized easily.
B. Experience	* Mention that after gaining experience, some draftsmen wrongly invent their own abbreviations. Their symbols may mean little to the reader of the map and could even cause confusion.
C. General abbreviations	* Inform the class that certain abbreviations are used in highway work. Many of these will not be covered here since they pertain to the more technical data which will be encountered in later courses.
	* State that some of the abbreviations covered at this time will be found on the U.S. Geological Survey maps and on many highway plans.
	* Have the students study the Table of Abbreviations on the Standard Symbols and Abbreviation Sheet.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

1. Alinement

* Discuss each symbol under alinement and emphasize that each one is designed for easy recognition and interpretation.

Ah.	= Ahead
Beg.	= Begin
Bk.	= Back
B_L	= Base line
C_L	= Centerline
Cor.	= Center correction of V.C.
C.S.	= Point of curve to spiral
Dc	= Degree of curve
Def.	= Deflection
e	= Maximum superelevation
Eq.	= Equality
Ext.	= External
H.S.D.	= Headlight sight distance
L	= Length
P.C.	= Point of curve
P.I.	= Point of intersection
P.O.L.	= Point on line
P.O.T.	= Point on tangent
P.S.D.	= Passing sight distance
P.T.	= Point of tangent
P.V.I.	= Point of vertical intersection
R	= Radius

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

S.C.	= Point of spiral to curve
S.S.D.	= Stopping sight distance
S.T.	= Point of spiral to tangent
T	= Tangent (Ts = spiral; Tc = compound)
T.Pt.	= Tie point
T.S.	= Point of tangent to spiral
V.C.	= Vertical curve
° ' "	= Degrees, minutes and seconds (such as 6°26'33")

2. Section notes

* Explain briefly the meaning of cross-sections, noting that this subject will be covered in the surveying unit.

B.C.	= Bottom of curb
B.M.	= Bench mark
B.O.	= Bottom of opening
Elev. or El.	= Elevation
H.I.	= Height of instrument
O.S.	= Original surface
P.M.	= Procedure manual
S.S.C.	= Same slope continues
T.C.	= Top of curb
T.H.W.	= Top of headwall
T.O.	= Top of opening
T.P.	= Turning point

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

3. Topography (Pavement)

* Indicate that these items are probably the most widely used since they cover visible features.

A.C. = Asphalt concrete

Bit.Mac. = Bituminous macadam

Brk. = Brick

Conc. = Concrete

E.P. = Edge of pavement

Pav't = Pavement

Rd. = Road

S.S. = Shoulder stabilization

4. Topography (Drainage)

* Point out the importance of abbreviations in an area where a concentration of drainage facilities is found.

B.B. = Bottom of bank (stream)

C.B. = Catch basin

C.I. = Curb inlet

C.I.P. = Cast iron pipe

C_L Strm. = Centerline of stream

C.M.P. = Corrugated metal pipe

C.P. = Concrete pipe

C.R. = Curb receiver

Culv. = Culvert

D.I = Drop inlet

D'Xing = Ditch crossing

E.H.W. = Extreme high water

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

E.S. = End section

H.W. = Headwall

Inv. = Invert

M.H. = Manhole

M.H.W. = Mean high water

O.C.M.P. = Oblate corrugated metal pipe

O.H.W. = Ordinary high water

R.C.P. = Reinforced concrete pipe

T.B. = Top of bank (stream)

T.G. = Top of grate

V.C.P. = Vitrified clay pipe

V.T.P. = Vitrified tile pipe

5. Topography (Utilities)

* Explain that these abbreviations assist the designer to locate utilities within a minimum of space.

G. = Gas

G.P. = Guy pole

G.S.B. = Gas service box (house line)

G.V. = Gas valve (main line)

H.P.G. = High pressure gas

Hyd. = Hydrant

L.P. = Light pole

L.P.G. = Low pressure gas

P.P. = Power pole

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Tel.P. = Telephone or telegraph pole
	W. = Water
	W.S.B. = Water service box (house line)
	W.V. = Water valve (main line)
6. Topography (Miscellaneous)	* Write each abbreviation on the chalkboard and explain its meaning.
	Abut. = Abutment
	Bldg. = Building
	Br. = Bridge
	Brk.Ho. = Brick house
	C.B.Ho. = Concrete block house
	C-C = Center to center
	CR = County road
	C.R.W. = Concrete retaining wall
	D = Deed distance
	DM = Direct measurement
	Drwy. = Driveway
	Fd. = Foundation
	Fr.Ho. = Frame house
	Ho. = House
	I.P. = Iron pin or iron pipe
	M = Measured distance
	Mon. = Monument
	N & R = Nail and red

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	N & W = Nail and washer
	P_L = Property line
	Por. = Porch
	RR = Railroad
	R.O.W. = Right-of-way line
	SH = State highway
	Spk. = Spike
	St. = Street
	Stk. = Stake
	Sto.Ho. = Stone house
	Sty. = Story
	SW. = Sidewalk
	T.L. = Tree line
	W.W. = Wingwall
II. Lettering	* Mention that the lettering on the topographic map is simple and dignified and is used mainly to convey information. (Ref. C, p. 93)†
A. Style	* State that in most highway work the style of lettering is either upright or inclined commercial gothic or upright or inclined modern roman. Show examples of each on the chalkboard.
	* Mention that gothic is referred to as single-stroke lettering, which means the width of the straight and curved lines of the letter are the same width as the stroke of the pen or pencil.

†Reference citations are shown on page 1.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Note that the modern roman type requires more time and recently it has been reserved only for titles or for some predominate feature of a map.
	* Recall that inclined letters are at an angle of about 70° with the horizontal.
B. General proportions	* State that the height of letters on a topographic map should be proportionate to the size of the drawing.
	* Indicate that a certain amount of flexibility is used when compressing or extending lines of letters.
C. Technique	* Show the correct way to hold a pencil for both the vertical strokes and for horizontal strokes. (Ref. A, pp. 85-86)
1. Lettering pens	* Point out that the choice of a penpoint depends on the draftsman, the paper used, and the size of lettering required. In general, a Henry tank pen, Gillott's points, Hunt's points, or any of the Speedball series is used.
	* Stress that a good penpoint has enough resistance to normal pressure to permit the drawing of curved and stem strokes of uniform width. A flexible penpoint is unsatisfactory for lettering. (Ref. A, p. 93)
2. Proportion	* Show how every letter has a definite relationship of width to height.
	* Mention that each letter is envisioned on a background block consisting of 36 little squares (6 vertical and 6 horizontal). The proportion of each part of a letter should be learned visually. (Ref. A, p. 86)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Order of strokes	* Demonstrate the entire alphabet by family groups, showing the order of strokes in the construction of each letter or number.
a. I, H, T group	* Explain that the I is the foundation stroke. The H is a square—5 small squares by 5 small squares. The top of the T is 6 small squares across. (Ref. A, p. 86)
b. L, E, F group	* Show that the L is made in two strokes. A third stroke places the top of the E, and a fourth stroke is 2/3 as long as the top and base. The F has the same proportions as the E. (Ref. A, p. 86)
c. N, Z, X, Y group	* Stress that the parallel sides of the N are made first. The Z and X are both started inside the background block at the top and go all the way out at the bottom. This places the crossing of the X above center. Note that the junction of the Y is at the center. (Ref. A, p. 86)
d. V, A, K group	* Show that the V and A are both one background square wide. The A bridge is 1/3 up from the bottom. The second stroke of the K strikes the stem 1/3 up from the bottom. The third stroke of the K is aimed from the top of the stem. (Ref. A, pp. 86-87)
e. M, W group	* Point out that the M is made in 6½ small squares and add that the W is made in 8 small squares. (Ref. A, p. 87)
f. O, Q, C, G group	* Mention that the O, Q, C, and G are letters of the O family and are made as full circles. (Ref. A, p. 87)
g. D, U, J group	* State that a common problem with the D is the failure to draw the stem horizontally. The J is a portion of the U. (Ref. A, p. 87)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
h. P, R, B group	* Point out that the middle lines of the P, R, and B are in the center of the stem. (Ref. A, p. 87)
i. S, 8, 3 group	* Emphasize that the S, 8, and 3 are all formed in the same way.
	* Note that a perfect 3 can be finished into an 8 and caution that a flat top should never be used on the 3. (Ref. A, p. 87)
j. 0, 6, 9 group	* Show that the cipher is 5/6 as wide as the O. The 6 and the 9 have the same curve as the cipher, with the lobes at 2/3 of the height. (Ref. A, p. 87)
k. 2, 5, 7, & group	* Demonstrate the problem of having the reverse curve of the 2 crossing exactly at the center of the block. The bottom of the 2 and the top of the 5 and 7 are horizontal straight lines. The stem of the 7 ends directly below the middle of the top. The ampersand requires practice to make it carefully balanced. (Ref. A, p. 87)
4. Fractions	* Explain that fractions are always made with the horizontal bar. The total height of the fraction is twice as high as one number. The numerator and the denominator are made 3/4 as high as one number. (Ref. A, p. 88)
5. Lowercase letters	* Mention that lowercase letters are used extensively on topographic maps. (Ref. A, pp. 88-89)
	* Emphasize that the basic form of the lowercase letters is a combination of a circle and a straight line.
	* Demonstrate the construction of the lowercase letters in a comparable fashion as with the capitals.

FOREWORD

The Office Occupations Program as it is designed at the Gila River Career Center, has as its salient objective the preparation of students to get and hold jobs in office occupations. These jobs, listed in graduated order of training time required, are receptionist, file clerk, clerk-typist, and stenographer.

While achieving this objective the program has taken into consideration certain factors that are inherent to all training programs as well as those inherent to the Gila River Center in particular. These factors have dictated that the program design meet the following needs: (1) student termination at any time during the training cycle, (2) student transfer to different job classifications, (3) student transfer to Central Arizona College, (4) rapid feedback on each student's progress through the total program to the student, instructor, and counselor (5) maximum of individualized instruction, (6) administrative control.

Students, particularly adult students, often choose to terminate their training before completion of a total program. In order to allow for this possibility, the program is designed to provide terminal points within the total program. This allows the student to terminate his training with some saleable skill acquired. For example, a student wishes to train as a clerk-typist (see "Student Flow Chart" page vi), but after only 150 hours of training he decides to quit. The counselor needs only to convince him to continue for (32) more hours of occupational training and he can quit with the skills required of a receptionist.

The design allows for the same situation in reverse. Suppose a student acquires the necessary skills required of a receptionist and wishes to continue. He simply goes back into the process taking the first unit required for file clerks.

The desire of students to transfer to a college curriculum at Central Arizona College is provided for through the basic education block. This block offers the student individual aid in communications, reading and math geared to passing the G.E.D. test.

Emphasis on individualized instruction necessitates the need for the fourth factor, i.e., the need for rapid feedback. With students following different paths and progressing at different speeds, counselors and instructors must have instant information on student progress if they are to tailor instruction to meet individual needs. This factor has been designed through use of computerized instructional management. The system, called Individual Program Control (IPC), provides the student, the counselor, and the instructor with up to the minute information on student progress in the total program.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
6. Left-handed person	* Advise the class that the left-handed person can reverse certain strokes but that he should exercise caution in inclined lettering. (Ref. A, pp. 90-91)
7. Composition	* Point out that composition is the selecting, arranging, and spacing of appropriate styles and proper sizes of letters. (Ref. A, pp. 91-92)
	* Note that each letter is spaced according to its shape and the shape of the letter preceding it.
8. Guidelines	* Demonstrate the use of the lettering triangle or the Ames Lettering Instrument. (Ref. A, p. 84)
	* Explain how the holes are used to provide guidelines for any size of lettering.
	* Show how the slant height is set on the guidelines.
D. Types of lettering	* Indicate that different types of lettering are used for the various elements of the topographic map.
1. Subdivisions	* Note that the names of states, counties, and townships are shown in upright capital letters.
	* State that the most important subdivision on the map is noted by the largest letters and that the size of the letters depends on their location on the map.
	* Note that the names of small towns and villages are lettered in upright lowercase letters. (Ref. C, p. 115)
2. Hydrography	* Point out that the names of hydrographic features are lettered in inclined capitals. The importance of the feature determines the size of the letters used.

313 OF 327
ED
056 238

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Stress that water will ruin a tracing, so precautions must be taken for sweating hands and arms during hot weather.
b. Cleaning	* Note that only a volatile liquid such as benzene or carbon tetrachloride will clean tracing cloth. These agents remove all pencil marks, dirt, and smudges but they give off poisonous fumes so care must be taken in using them. (Ref. A, p. 398)
c. Erasing	* Explain that erasures are more easily made on the smooth side, but the dull side is tougher and will withstand more erasing. If an eraser other than the ruby is used, the fibers of the cloth will be broken. * Demonstrate erasing with different types of erasers on both the smooth side and on the dull side of the cloth. When the fibers are broken, rub the spot with talc and cover with collodion to prevent the cloth from spreading any ink. * Indicate that soapstone will also place a slick, smooth finish on damaged areas.
d. Inking	* Note that all pens are filled by means of a quill or dropper and are never dipped. Caution the class to keep the ink bottle off the board and to the right and tell them to be sure to cap the bottle when it is not in use. * Stress the importance of inking exactly over the pencil lines. * Indicate that the order of inking on a tracing is as follows (Ref. A, p. 398; Ref. B, p. 52): 1. Full line circles and arcs 2. Dotted circles and arcs

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	3. Irregular, curved lines 4. Straight lines; first horizontal (top to bottom), then vertical lines (left to right), and last inclined lines, the uppermost first. 5. Dotted lines in the same order as above 6. Centerlines 7. Crosshatching 8. Pencil guidelines for lettering 9. Lettering 10. Border 11. Check the tracing for any errors and/or omissions.
e. Practice	* Distribute a small piece of tracing cloth to each member. Have them place it over a map or drawing and ask them to trace with ink a portion of the material underneath.
C. Pencil transfer	* Discuss the pencil transfer method of copying a drawing. (Ref. A, p. 643; Ref. C, p. 179)
D. Glass top drawing board	* Describe the glass top drawing board fitted with lights and explain how it is used for copying a drawing. (Ref. C, pp. 179-180)
E. Pantograph	* Exhibit a pantograph and explain how it is used to make duplicate, enlarged, or reduced copies of a drawing. (Ref. C, pp. 180-181)
III. Duplicating Drawings	* Point out that the simplest method of duplicating a drawing is a direct print from the original tracing by means of a processed paper.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Blueprinting	* Explain the blueprinting process. (Ref. A, p. 404; Ref. B, p. 652; Ref. C, pp. 185-186)
1. Advantages	* Note that economy of equipment and operation makes blueprinting a good method of duplicating drawings. It was once the most widely used process.
2. Disadvantages	* Point out that the blueprint process is time consuming. The process involves the use of chemicals in solution. So the resulting print is wet and must be dried before using.
B. Van Dyke process	* Explain that the Van Dyke process involves the printing of a negative first. (Ref. A, p. 404; Ref. B, pp. 653-654; Ref. C, pp. 186-187)
1. Advantages	* Note that the negative may be used on Van Dyke paper or on ordinary blueprint paper. * Explain that the negative may be used many times without harming the original drawing. * Indicate that erasures may be made on the negative without changing the original.
2. Disadvantages	* Point out that the Van Dyke method is a wet, chemical process and is time consuming.
C. Ozalid process	* Describe the ozalid process and indicate that it is an excellent method for reproducing drawings. (Ref. A, p. 405; Ref. B, p. 654)
1. Advantages	* Indicate that the process uses a dry ammonia vapor, so it is not messy. * State that a print is made in a matter of seconds and is an exact copy of the original with no distortion.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Note that the operator needs little training. * Mention that the process will print milars or paper transparencies, which in turn can be used as originals. * State that wide and long originals can be printed.
2. Disadvantages	* Mention that the ozalid printing machine has a high initial cost. * Explain that an exhaust system must be provided to blow out the ammonia fumes.
D. Photocopying	* Describe the photocopying process. * Indicate that this process can be used to enlarge or to reduce the scale of the original. (Ref. A, p. 405; Ref. B, p. 657; Ref. C, p. 187)
E. Other process	* Explain the lithoprinting, line etching, typographic etching, and photolithographic processes but point out that they are unsuitable for highway plans. (Ref. B, pp. 652-658) * Indicate that these processes are suitable for some elements of industrial practice. * State that the U.S. Geological Survey (U.S.G.S.) maps are made by a photolithographic process.
F. Samples	* Distribute samples of the various duplicating processes and explain each with information about printing time, cost, and value. * Ask the class to make their own analysis of the material and elicit comments.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* State that blue india ink is used on hydrographic features, red opaque paint for all new work, and black for all existing features.
V. Meridian	* Note that any map, regardless of size or shape, must have some orientation from the north.
	* Indicate that magnetic north is shown by a half arrow and true north is shown by a full arrow.
	* Caution the class not to make the north point too ornamental or heavy. It should be simple and proportionate to the size of the drawing. (Ref. C, p. 120)

QUESTIONS FOR REVIEW

1. Explain the meaning of the following abbreviations:

(a) R	(b) RR	(c) CR	(d) N & R
(e) R.O.W.	(f) R.C.P.	(g) Rd.	(h) C.R.W.

2. Would the O.S. necessarily be disturbed if a C.M.P. with an E.S. were to replace an R.C.P. with a low Inv.?

3. Why is it not feasible to use ornamental lettering on topographic maps?

4. Where is the modern roman type of lettering used?

5. Which letter occupies the largest space?

6. Identify the difference between the letter O and the cipher 0.

7. List three important factors to follow when drawing fractions.

8. At what angle to the horizontal is an inclined letter?

9. What is the order of inking on a topographic map?

10. Describe a true north arrow.

22113

Lesson 8 - Techniques of Reproducing Drawings

OBJECTIVE

To understand the techniques of reproducing drawings

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. The Original Drawing	* Note the amount of time and work required to produce a topographic drawing. * Point out that it may be necessary to have a number of identical drawings for a given phase of work.
II. Copying Drawings	
A. Pricking	* Explain that if only one more copy is required, the second drawing could be expedited by pricking points with a fine pointed instrument through the original map into the new copy.
B. Tracing	* Point out that the most common method of copying drawings is by tracing the lines of the original (pen or pencil) in india ink onto tracing paper or cloth. (Ref. C, pp. 181-182)†
1. Tracing cloth	* Mention that tracing paper lacks strength and stability. So tracing cloth should be used for any permanent work. (Ref. A, pp. 395-398) * Explain that tracing cloth has one dull side and one smooth side, but it is possible to order cloth which is dull on both sides.

†Reference citations are shown on page 1.

22115

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Indicate that the smooth side is the working side. Most draftsmen use the dull side because it takes ink and pencil lines more readily, erases more easily, and produces less glare.
	* State that when ink is used on the smooth side, any pencil shading must be placed on the back, or dull side, of the sheet.
	* Distribute samples of different types of tracing cloth and tracing vellum and tell the class to make both pen and pencil marks on the different samples.
2. Procedure	* Caution the class to be certain that the tracing cloth is stretched smoothly and evenly over the pencil drawing. (Ref. C, pp. 183-184)
	* Explain that the working side of the cloth may be dusted with chalk dust, talcum powder, or prepared pumice. This is then rubbed off, which removes the waxy film and permits an easy flow of ink.
	* Add that when the finished tracing is used for reproduction, all inking should be a little heavier than if it were for a single product.
	* Mention that pencil guidelines made with a soft lead prevent an even flow of ink on the paper.
a. Problems	* Note that tracing cloth is very sensitive to changes in humidity and temperature. When the entire map or plan cannot be finished in one day, work should be segregated to a selected area. Otherwise the next day the tracing would have to be reoriented on the original map.

22116

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Mention that for lettering winding creeks the name follows only general curves. (Ref. C, p. 116)
3. Natural land features	* Explain that the names of prominent, natural land features are shown in upright capitals but smaller than those used for political subdivisions.
	* Note that the names of small valleys, peaks, and islands use lowercase upright letters. (Ref. C, pp. 116-117)
4. Public works	* Stress that the names of railroads, highways, tunnels, bridges, and ferries are lettered in inclined capitals. (Ref. C, p. 117)
5. Map titles	* Note that only upright roman is used for map titles.
	* Demonstrate the method of locating the title box on a map.
	* Describe the information required in the title box on a map. (Ref. C, pp. 117-120)
E. Rules	* Point out the rules and procedures to follow when lettering topographic maps (Ref. C, pp. 111-113): 1. Place names carefully so that the topographical symbols are not covered or crowded. 2. Place names to the right or left of the object. 3. In general, make names parallel to the lower border. 4. Letter railroads, highways, and utility lines parallel and close to their boundaries. The letters are placed with ordinary spacing, but the words themselves should be separated by a space equal to the length of the longest word in the title.

22111

ASSIGNMENT

1. Study pages 394-399 and pages 404-405 in Ref. A.

2. Ask the students to prepare a penciled topographic map of any design on drawing paper. Stipulate that the scale should be 1 in. = 50 ft. and that the following features should be shown:

   (a) Highway
   (b) River
   (c) Island
   (d) Railroad
   (e) Bridge
   (f) Town line
   (g) Bench mark
   (h) High tension lines
   (i) Magnetic north

   Add that proper lettering is to be used in designating the various features of the map, including the title and scale and that the map will be checked at the next class.

INSTRUCTOR'S NOTES

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	5. Letter utility lines and streams to read from the bottom of the map.
	6. Extend the names of elongated forests, swamps, and bodies of water in the direction of the long dimension and have the lettering extend almost its entire length.
	7. If a name does not fit because of the small scale being used, place it in the legend of the map.
	8. Study the relative importance of all the names before beginning to letter.
III. Order of Inking	* Mention that all topographic draftsmen do not follow the same pattern in inking maps. The following fundamental principles, however, must be used (Ref. C, pp. 109-111):
	1. Certain classes of symbols having no option of location—towns, houses, railroads, highways, and property lines—are inked first.
	2. All names are lettered next because they have precedence over the information which follows.
	3. Contours are inked next. They are drawn through houses and highways except on large scale maps.
	4. Contour elevations, all water features, and vegetation symbols are then inked.
IV. Color Inking	* Explain that while the topographic map is made up in several colors to denote different features, the highway map is less demanding.

22112

Administrative control is provided for through a subsystem within IPC. This subsystem utilizes the method of cost effectiveness analysis to insure that the total program as well as the office occupations program is meeting its stated objectives.

MICROCOPY RESOLUTI
NATIONAL BUREAU OF S

ON TEST CHART

TANDARDS-1963-A

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* State that the geographical center of the United States including Alaska and Hawaii is in Butte County, South Dakota, 14 mi. east of the junction of the borders of South Dakota, Montana, and Wyoming at latitude 44°58' N. and longitude 103°46' W.
	* Point out that the geographical center of the 48 states is near Lebanon, in Smith County, Kansas at the intersection of latitude 39°50' N. and longitude 98°35' W.
	* Mention that the geographical center of New York State is in Madison, southwest of Utica.
II. U.S. Geological Survey (U.S.G.S.)	* State that the U.S. Geological Survey, commonly called U.S.G.S., is a bureau of the U.S. Department of the Interior, established by Congress in 1879. (Ref. F, p. 3)
	* Point out that this bureau has the following four divisions: 1. Topographic 2. Geologic 3. Conservation 4. Water Resources
A. Topographic division	* Stress that the mission of the topographic division is to collect, publish, and distribute data concerning the physical features of the United States.
1. National Topographic Map Series	* State that the topographic division is responsible for the delineation of the physical features of the United States as quadrangles of the National Topographic Map Series.
	* Emphasize that these multi-purpose three-dimensional maps provide basic information for engineering projects, mineral and water resource studies, national defense, and industrial and community planning. (Ref. F, pp. 6-8)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Revisions	* Note that when maps require revision, the area is surveyed again and remapped at a larger scale.
III. U.S.G.S. Map	
A. Projection	* Remind the class that these topographic maps are a polyconic projection and the greatest accuracy is found close to the center meridian. The information is located in the lower margin of the map.
B. Mapping	* State that much of the work in mapping is done by aerial photography and that contours are placed on the map by stereoscopic plotting. (Ref. F, pp. 10-11)
C. Plan of development	* Explain that the country is divided into quadrangles bounded by parallels of latitude and meridians of longitude. These quadrangles are mapped in different scales, depending on the use to be made in developing that particular area.
D. Scale	* Recall the definition of scale or the representative fraction as the fixed ratio between linear measurements on the map and corresponding distances on the ground. (Ref. F, pp. 4-6)
	* Point out that the graphic scales are printed in the center of the lower margin of each sheet. The scale shows distances in feet, kilometers, and miles.
E. Coverage	* Explain that many of the older U.S.G.S. quadrangles covered 15' longitude and 15' latitude. Today quadrangles of this size, based on recent data and drawn by photogrammetric methods, are generally used for sections of sparce population like the Adirondack Mountain area in northeastern New York State.
	* Indicate that the scale of this map is 1:62,500 or 1 in. = 1 mi.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Note that the common contour interval is 20 ft.
	* Emphasize that to provide greater accuracy many of the 15' quadrangles now have been divided into quarters that cover 0°7'30" of longitude and 0°7'30" latitude. Generally this size map is replacing the 15' quadrangle.
	* Indicate that the scale of the map is 1:24,000 or 1 in. = 2000 ft.
	* State that the common contour interval is 20 ft.
	* Remind the class that in this latitude (New York State) 1 degree of latitude is much longer in miles than 1 degree of longitude.
F. Grids	* Explain that the map is divided and marked into a grid system at specific minutes of latitude and longitude depending on the scale.
	* State that the longitude lines or vertical grid lines are true north lines and the parallels of latitude are true east and west lines.
	* Describe the difference between true north and magnetic north. Point out that a complete study of these will be made in the unit on surveying.
	* Note the true north and magnetic north symbols in the lower margin and explain the principle of declination. Point out that this topic will be covered in detail in the unit on surveying.
G. Coordinate system	* Explain the New York State coordinate system and show how it is used and marked on the map.
	* Add that the 1,000-meter Universal Transverse Mercator gridticks are shown in blue on all four edges of the map.

QUESTIONS FOR REVIEW

1. What is the value of the pantograph for ordinary map work?

2. When should soapstone be used on tracing cloth?

3. What is the order of inking a tracing?

4. Why is it incorrect to dip a pen into india ink?

5. What is the best process of duplicating drawings available to the highway draftsman?

ASSIGNMENT

1. Study pages 97-103 in Ref. A.

2. Tell the students to ink on tracing cloth the corrected topographic map of the preceding lesson. Add that these will be printed by the ozalid process.

INSTRUCTOR'S NOTES

22121

Lesson 9 - Map Projections

OBJECTIVES

1. To introduce the concept of projecting a sphere onto a flat surface
2. To acquaint the student with the different methods of map projection

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Location Factors	* State that some type of a geographical grid is necessary to locate specific points on the surface of the earth.
A. Coordinate system	* Sketch on the chalkboard a simple x-y axes and explain a basic coordinate system. * Show how a point may be located or referenced from another point by the use of a coordinate system.
B. Latitude	* Explain that parallels of latitude are imaginary horizontal lines running parallel to the Equator and extending to the poles. * Demonstrate on a globe how these parallels become smaller as they approach the poles. * Describe how these lines are numbered in degrees from 0 at the Equator to 90 at the poles.
C. Longitude	* Explain that the meridians of longitude are imaginary vertical lines running north and south around the earth.

22122

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Physical facts	* Emphasize that the following facts must be considered before mapmaking is attempted: 1. The earth is considered a sphere. 2. All meridians are of equal length and meet at the poles. 3. All parallels are complete circles which decrease in length as they approach the poles. 4. The distance between all parallels is the same along all meridians. 5. The distance between all meridians is the same along a given parallel. 6. Each meridian crosses the Equator and all parallels at right angles. * Suggest that no projection of the earth on a flat surface could follow all of these requirements. So to achieve one purpose something else must be given up.
B. Problems	* Explain that it is impossible to show any portion of the earth's surface on a flat map because of the sphericity of the earth. This may be compared to the flattening of a piece of orange peel or flattening a half of a rubber ball. * Mention that a flat map of the earth cannot be drawn without some kind of squeezing, stretching, or tearing. * State that regardless of size every map has some type of distortion. This is ignored in a survey of a small piece of property.

22124

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Emphasize that methods have been developed to depict a portion of the earth's surface on a flat map.
C. Projections	* State that a projection is the representation of an object on a flat surface.
	* Point out that any map of a portion of the earth's surface is a projection. (Ref. D, p. 937)†
	* Explain that each type of projection satisfies a certain set of conditions.
1. Gnomonic	* Describe the gnomonic projection as a geometric projection to a plane tangent to the earth's surface at any point with lines radiating out from the center of the earth and intersecting the tangent plane. (Ref. D, p. 938)
	* Note that this projection shows the great circles (meridians) as straight lines, which makes this very useful in navigation.
	* Indicate that this projection is true only in the area that is close to the point of tangency. Everything else is distorted.
2. Stereographic	* Show how the stereographic projection is a geometric projection to a plane tangent to the earth's surface at any point with lines radiating from a point on the earth's surface opposite the point of tangency. (Ref. D, p. 939)
	* State that this projection is excellent for showing a picture of a hemisphere but the areas are not true.
3. Mercator	* Explain that the mercator projection is a cylindrical projection made by projecting all points from

†Reference citations are shown on page 1.

22125

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	the earth to a cylinder which then is unrolled. This shows all parallels and meridians as straight lines and at right angles to each other which is perfectly true only at the Equator. (Ref. D, p. 942)
	* Explain that Greenland, which is about 1/8 the size of South America, appears larger than South America on this type of map.
4. Conic	* Point out that the conic projection places the earth in a cone and that projections are made from the earth to the cone. In this projection all the parallels are shown as curved lines.
	* State that this projection has its greatest accuracy at the line of contact. (Ref. D, p. 939)
5. Polyconic	* Explain that the polyconic projection consists of placing the earth in a series of cones, which then are unrolled and fitted together.
	* Point out that this projection is sufficiently accurate for maps of large areas. Also it has been adopted by the U.S. Geological Survey for the making of topographic maps. (Ref. D, pp. 940-942)
	* State that a vertical straight line marks a central meridian. This meridian is divided accurately so that the parallels are spaced correctly. Each parallel is divided truly and curved lines are drawn through these points to form meridians.
	* Indicate that the distortion is very small near the central meridian, which makes it excellent for small areas.

22126

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
6. Other projections	* Emphasize that there are other types of projections, each achieving a specific purpose. Most of these are called Conformal Projections.
	* Note as an example the Lambert Conformal Conic Projection, a simple conic projection except that the cone cuts the surface of the earth along two parallels of latitude called Standard Parallels. A map of the United States in this projection has an error of less than 2% at any point. (Ref. D, p. 942)
III. Highway Maps	* Indicate that the financial capability of contractors restricts new highway projects to relatively short distances. Thus the problem of error, due to projection, that occurs within the length of the project can be disregarded.
	* Note that it is important to coordinate the highway line when a long stretch of highway is built, like the New York State Thruway.
A. Convergency of meridians	* Explain that in survey work the convergency of meridians will be computed for a line run at a certain latitude. If this were not done, it would be impossible to coordinate any two projects.
B. Highway planning	* State that the most pertinent information for the location of a new highway will come from a U.S.G.S. map. Thus the system of projection and orientation is readily available.

QUESTIONS FOR REVIEW

1. Explain in terms of latitude and longitude why no projection of the earth on a flat surface can be precise.

2. Why did the U.S. Geological Survey select the polyconic projection for their use?

22127

UNIT CODE NUMBERS AND SUGGESTED
TIME ALLOCATIONS FOR ALL JOB
CLASSIFICATIONS

The following table shows individual unit titles, their respective code numbers, and suggested time allocations for each of the job classifications to which they relate.

		JOB CLASSIFICATIONS			
UNIT CODE #	TITLE	Stenographer	Clerk-Typist	File Clerk	Receptionist
-01	Occupational Orientation	5- 7 Hrs	5- 7 Hrs	5- 7 Hrs	5- 7 Hrs
-02	Fundamentals of Typing	70-85 Hrs	70-85 Hrs	70-85 Hrs	70-85 Hrs
-03	Office Equipment	20-30 Hrs	20-30 Hrs	10-15 Hrs	10-15 Hrs

Lesson 10 - U.S. Geological Survey Maps

OBJECTIVE

To provide information necessary to interpret the U.S. Geological Survey maps

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. U.S. Coast and Geodetic Survey	* Explain that the U.S. Coast and Geodetic Survey is a bureau of the Department of Commerce. The bureau's geodetic branch is involved with the precise measurement of the size, shape, and curvature of the earth. The U.S. Coast and Geodetic Survey is often confused with the U.S. Geological Survey.
	* Explain that the U.S.C.G.S. surveys establish exact positions and altitudes of rivers, mountains, cities, and other natural or cultural features. This information is supplied to engineers, surveyors, and to the U.S.G.S. for use in mapping, establishing boundaries, and planning highways and railroads.
	* Note that the geodetic center of North America is at the Meade's Ranch Triangulation Station in Osborne County Kansas, 12 mi. north of Lucas, Kansas. This point (lat. 39°12'26.686" N. and long. 98°32'30.506" W.) is the point of origin for all governmental mapping in the United States, Canada, and Mexico. (Ref. D, p. 381)†
	* Point out that the geographical center of North America is in Pierce County, North Dakota, at latitude 48°10' N, and longitude 100°10' W.

†Reference citations are shown on page 1.

22129

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Point out that the meridian of longitude passing through the Royal Observatory at Greenwich, England is called the zero meridian or Prime Meridian.
	* Mention that the other meridians are numbered from this zero point to 180° E. and 180° W.
	* Show the position of certain meridians on the globe.
D. Use of parallels and meridians	* Illustrate how any point on the surface of the earth can be located by its latitude and longitude.
1. Distance versus degrees	* Show that one degree of latitude is equal to 69.4 mi. This is determined by dividing the earth's circumference at the Equator, about 25,000 mi., by 360°.
	* Explain that 1 degree of longitude is not the same at different latitudes. Note the equivalencies below for 1 degree of longitude at various latitudes: 1. Equator - 69.17 mi. 2. 30° - 59.96 mi. 3. 60° - 34.67 mi. 4. 80° - 12.05 mi. 5. 90° - 0.0 mi.
	* Note that this presents problems in highway orientation. These problems will be brought out in the unit on surveying.
II. Mapmaking	* Relate that for centuries man has tried to make a flat map that is accurate.
	* Explain that a flat map cannot be made correct in all respects, because of the curvature of the earth.

22123

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
H. Features of maps	* Stress that the features shown on the U.S.G.S. maps may be divided into three groups: 1. Hydrographic 2. Relief 3. Culture * State that certain features, like vegetation, cannot fit on the maps because of the scale used.
1. Symbols	* Review the symbols that are used on U.S.G.S. maps. (Ref. F, pp. 16-17)
2. Colors	* Point out that U.S.G.S. maps use: 1. Black for culture 2. Brown for relief 3. Blue for hydrography 4. Red for highway type differentiation. * State that small streams or small canals are shown by a single blue line and larger streams by a double blue line. Large bodies of water are actually colored blue. Intermittent streams (whose beds are dry for a large part of the year) are shown by lines of blue dots and dashes. (Ref. F, pp. 14-15)
3. Datum	* Explain that the datum used for contours on U.S.G.S. maps is zero altitude or mean sea level. * Discuss how the contours indicate the shapes of slopes, hills, mountains, and valleys. Point out the location of the summit or valley elevation. * Indicate that the contour interval is located in the lower margin of the map. * Add that the bench marks are noted to the nearest foot. Explain that they are listed in a governmental publication by level runs in exact figures to three places.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Note the triangulation points on the map and explain how and why they were so placed. * Point out that the intersections of highways are marked with the elevation of the ground at that point to the nearest foot. * Note that the elevation of the surface of a lake is shown at ordinary high water level. (Ref. F, pp. 12-13)
4. Highways	* Explain that the color code and size of line indicates the type of highway. This legend appears in the lower margin of the map. * Point out that as a highway reaches the border of the map, an arrow indicates its direction and distance to a terminal point. * Mention that the names of highways and roads are the local names attached to such roads. The numbers of the roads are designated by either the town, county, state, or the U.S. classification system.
5. Political subdivisions	* Indicate that the names of counties, cities, and towns usually are identified by large letters that stretch across the entire political subdivision. The limits of these areas are shown by marked boundaries.
I. Quadrangle information	* Point out that the name of the quadrangle, the name of the state, and the size of the series appear in the upper margin of the map. The quadrangle is named when the map is a quarter subdivision. (Ref. F, p. 18)
1. Area name	* Note that the area name and the coverage by the latitude and longitude in degrees are located in the lower margin of the map.
2. Location sketch	* Point out the small sketch of the State with the rough location of the

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	quadrangle that appears in the lower margin of the map.
3. Dates	* Indicate that the date of the map, the date the aerials were taken, and the date of revision appear in the lower margin of the map.
4. Adjacent quadrangles	* Point out that the names of the adjacent quadrangles are shown in the margins of the map. The diagonal name in the corner identifies the quadrangle next to the one that is directly above the quadrangle being read.

QUESTIONS FOR REVIEW

1. Why is the U.S.G.S. topographic map called three dimensional?
2. What is meant by the representative fraction of a U.S.G.S. map?
3. What is the latitude and longitude covered in a U.S.G.S. map with a scale of 1:24,000?
4. What do the blue gridticks signify on the quarter section of a U.S.G.S. map?
5. What type of projection is used for a U.S.G.S. map?
6. How can the type of highway be determined from a U.S.G.S. map?
7. Explain what is meant by the datum of a U.S.G.S. map.
8. What is a triangulation point as used on a U.S.G.S. map?

ASSIGNMENT

1. Ask the students to list the vegetation, works of man, and utilities that appear on their copy of the U.S.G.S. map.
2. Have the students locate the lowest and the highest marked elevation and the lowest and highest contour on the quadrangle.
3. Ask the students to list all political subdivisions on the map.
4. Have the students locate two prominent spots on the map by latitude and longitude.

Lesson 11 - Plotting Field Notes (Transit)

OBJECTIVES

1. To emphasize the importance of interpreting correctly every detail of the field notes
2. To provide the necessary information to plot field notes

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Field Notes	* Emphasize that field notes are the most important single element in the entire operation of surveying. (Ref. D, p. 43)†
A. Permanent record	* Stress the fact that the field notes are the permanent record of a survey. A field record reinforced by memory is worthless. * Add that notes of apparent insignificance may someday be very valuable for design, construction, or a court case. * State that sometimes a survey is rerun and the value of the original notes will depend on their clearness and completeness.
B. Content	* Explain that field notes consist of numerical data, explanatory notes, sketches, dates, weather conditions, names and duties of the chief of party and his assistants, and the title and purpose of the survey. (Ref. D, p. 44) * Emphasize that field notes are entered as the work is being done. There can be no erasing. A single fine line is drawn through any mistake and the correction made, initialed, and dated.

†Reference citations are shown on page 1.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Indicate that this plotting will be checked by another person, using a different method, before it is inked.
2. Map details	* Suggest that the topographic details for the first two courses be plotted before the base line is completed.
	* Circulate about the class, explaining and correcting the methods and procedures of plotting map details.
3. Procedures	* Emphasize that the points indicated below should be followed when plotting: 1. Use a 2H pencil. 2. Use triangles for right angle offsets. 3. Place the symbol for a tree location at the point closest to the base line. 4. Account for each point plotted with either a symbol or letter. 5. Use triangles to square-in houses or buildings. 6. Be careful not to erase the wrong item. 7. Do not write on the field notes. 8. Place the date and the name of the plotter and checker on the sheet.

QUESTIONS FOR REVIEW

1. What information is placed in a field notebook just before the survey is begun?

2. Why do survey notes begin at the bottom of a page and progress to the top?

3. Why is the tangent offset method of plotting more accurate than the protractor method?

22139

4. Explain the function of a base line.

5. How should an error in a field notebook be corrected?

ASSIGNMENT

1. Instruct the students to finish plotting the base line and to plot the remaining topographic details as found in the survey notes.

2. Remind the students that this work is to be done in pencil and after the work has been carefully checked the pencil work will be inked.

INSTRUCTOR'S NOTES

22140

Lesson 12 - Plotting Field Notes (Cross-Sections)

OBJECTIVES

1. To understand the fundamentals of cross-sectioning and profiling
2. To provide the techniques for the plotting of a cross-section and a profile of a survey

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Profile Leveling	* Describe profile leveling as the process of determining the elevations of points at measured intervals along a fixed line. (Ref. A, pp. 611-612)†
	* Explain the use of the level for determining elevations and mention that leveling is covered in the unit on surveying.
A. Profile from centerline	* Sketch on the chalkboard a line A-B consisting of 10 full stations with an elevation at each station.
	* Draw a datum line and plot the elevations above to show the profile of the line A-B. (Ref. D, pp. 213-214)
B. Profile from plan	* Explain that it is often necessary to construct a profile from a plan. (Ref. C, p. 137; Ref. D, p. 643)
	* Give each student the locations of two points on their copy of a 7½-min. topographic map. Have them mark these points and connect them with a straight line, A-B.
	* Indicate that the procedure to follow when making a profile is:
	1. Place the topographic map firmly on the board.

†Reference citations are shown on page 1.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

2. Draw horizontal lines on a sheet of paper spaced in the vertical scale desired and number from the lowest to the highest contour line crossed by the line A-B.

3. Orient the horizontal lines until they are parallel to the line A-B.

4. Project all intersections of the line A-B with the contour lines crossed to the appropriate horizontal line on the paper.

5. Connect the series of points to complete the profile of the line A-B. (Ref. C, p. 156).

* Note that the horizontal scale is the same as that of the contour map.

II. Route Cross-Sections

* Explain by means of a base line how sections are run in the field.

* Point out that the mechanics of leveling will be covered in the unit on surveying.

* Explain that this method of taking sections is merely the construction of cross-profiles. (Ref. D, pp. 215-217, 638, 672)

* State that these cross-sections are required to furnish data for location studies and for estimating the quantities of earthwork involved.

A. Pattern

* Mention that these crosslines intersect the base line either at 50-ft. points or at even stations or at both these points.

* Point out that if these crosslines are short they are run out by eye perpendicular to the base line. But if they are long (100 ft. or more) they are set by the use of an instrument,

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

preferably a right-angle mirror. (Ref. D, p. 218)

B. Elevations

* Emphasize that the level is used to find the elevations of all points. (Ref. D, p. 218)

* Describe and illustrate the method of ascertaining the elevation of the height of instrument and the procedure of rod reading.

C. Notes

* Display some typical sheets of cross-section notes and explain the procedure of entry and control.

1. Reduction

* Emphasize that the rod readings are simply numbers and are of no consequence unless they are subtracted from the height of instrument. This subtraction gives the elevation of the point.

* Distribute to each student a sheet of cross-section notes and indicate that these notes are to be reduced to rod readings.

D. Plotting

* Demonstrate the plotting of a cross-section on the chalkboard and explain the following:

1. Selection of the size of paper or the scale of the cross-section

2. The direction of the plotting

3. The selection of a datum

4. The marking of the base line

5. The circling of the plotted points

6. The process of checking the points

7. Signing name and date

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Furnish each student with a sheet of cross-section paper and a sheet of level notes. Ask the students to plot one cross-section, beginning at the bottom of the sheet and then to exchange sheets so that points can be checked.

* Point out that after checking, the points are connected with lines in black ink. Indicate that the black ink line is known as the O.S. or the original surface.

III. Use

* Explain that the design engineer uses this procedure to plot the cross-section of the new highway. Add that this work is done in pencil.

* Show the importance of the cross-section in furnishing an excellent picture of the ground at each section.

* Elaborate on the sequence by which information is placed on those sheets throughout a project.

QUESTIONS FOR REVIEW

1. What is a profile?

2. Explain how to construct a profile from a plan when elevations are given.

3. Describe the process of obtaining a profile between any two points from an ordinary U.S.G.S. map.

4. What is the difference between a profile and a cross-section?

5. What is meant by note reduction?

ASSIGNMENT

Instruct the class to finish the reduction of the level notes which were used in this lesson. Add that these notes are to be plotted at a horizontal and vertical scale of 1 in. = 5 ft. and 1 in. = 10 ft. so that an evaluation may be made of the results. Remind the students that inking should not be done until the points have been checked.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Mention that notekeeping will be discussed in the unit on surveying, but emphasize here that the notebook should contain all the necessary information recorded in a form that will give only one interpretation—the correct one.
C. Examples	* Show the standard, coordinated looseleaf notebook used by the New York State Department of Transportation for many years.
	* Exhibit the new type notebook designed for use with the electronic computing machines.
	* Explain briefly how these notebooks are organized.
	* Point out the index marking on the outside of the book and on every page in the book (permanent record code).
	* Explain that the sheets on the left are used for base-line information while the sheets on the right are used for topographic information and sketches.
	* Mention that all information moves along the stationing from the bottom of the book to the top.
II. Mapping	* Note that the process of mapping is the precise plotting of horizontal control and the plotting, by less precise methods, of features called map details.
	* Point out that the process of mapping is in a way the reverse of the process of surveying. Data collected in the field is used to make a graphic representation of an area by showing features in the same relative location that they occupied on the ground, but to scale. (Ref. D, p. 445)

22137

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Horizontal control	* Review briefly the general idea of the base line and how it is used as the basis of the survey.
	* Recall briefly the methods used in plotting horizontal control. (Ref. D, pp. 446-450)
B. Details	* Emphasize that it is important to plot details within the proper limits of error. (Ref. D, pp. 466-468)
	* Mention that the accuracy of details affects the value of a set of plans.
1. Linear plotter	* Exhibit a plotter made of plastic and demonstrate how it is used to facilitate the locating of points at right angles to the base line.
	* Explain that the location of a detail is usually measured to the nearest foot. So a plotter that is accurate to the nearest foot will give satisfactory results.
	* Point out that when placed on the required station, this plotter can be set for any right angle offset, right or left of the base line.
	* Note that these plotters are usually homemade.
C. Practice	* Distribute individual sets of prints of the notes for a base-line survey. The base line should be at least 1,500 ft. long and consist of at least five transit points.
1. Base line	* Have each student estimate (or by drawing a small sketch) where to place the first course on their paper.
	* Direct the class to plot and draw the first and second course. This may be done by either the protractor or the tangent method at a scale of 50 ft. per in.

OFFICE OCCUPATIONS
STUDENT FLOW

Students preparing for one of the four job categories within the office occupations program would follow one of the paths illustrated below. The program is so structured as to allow students a choice, upon completion of specified performance objectives, of terminating or continuing into another job category path. Individual units are not necessarily presented in the sequence shown. A beginning student should, however, start with the Orientation Unit and progress from there.

Lesson 14 - Aerial Photography and the Digital Computer

OBJECTIVE

1. To discuss the rudiments of aerial photography
2. To understand the application of aerial photography to highway design and its use with the digital computer

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Aerial Surveying	* Explain that aerial surveying provides valuable information about the terrain and assists the highway engineer in analyzing proposed route locations and in designing new highways. (Ref. D, pp. 838-844)†
A. Concept	* State that the aerial survey records on film a segment of the earth's surface.
	* Indicate that aerial photographs consist of individual views in perspective that ordinarily use a 9 in. by 9 in. negative format. Along the line of survey, the individual views overlap each other by 60 percent, which affords two different views of anything on the ground.
	* Explain that a viewer is able to study these overlapping prints with stereoscopic instruments and distinguish the three dimensions of length, width, and height. The stereoscopic instrument used may be either a lens or mirror stereoscope.
	* State that the stereoscope is a mechanical device used to facilitate seeing in three dimensions. An observer can view two aerial photographs of the same object with his two eyes

†Reference citations are shown on page 1.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	in such a manner as to cause the photographs to fuse into a single, spatial model of the original object.
	* Demonstrate the simple stereoscope.
B. Photoreading	* Explain that photoreading is the process of recognizing certain features in the photograph either by eye or by instrument.
C. Photointerpretation	* Mention that photointerpretation is broader in scope than photoreading since it includes photoreading and is supplemented by the measurements from photogrammetry.
	* State that photointerpretating is a specialized art requiring knowledge of geology, climatology, hydrology, biology, and sociology.
	* Indicate that photoreading and photointerpretation are inference techniques and are qualitative.
D. Photogrammetry	* Define photogrammetry as the quantitative science of making vertical and horizontal measurements from aerial photographs.
	* Point out that these measurements are compiled into a topographic map directly or prepared for a digital computer.
II. Techniques of Photoreading and Photointerpretation	* Mention that cultural features are easily recognized on aerial photographs.
	* Show the class aerial photographs of the local area and have them locate features that are well known to them.
A. Buildings	* State that buildings are readily recognized by straight lines, sharp angular corners, and geometric roof patterns.
	* Explain that the type of building or functional use can often be inferred by its shape or position.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Note that commerical buildings are larger than residential buildings. High cost residential areas contain large lots, irregular shaped roof patterns, and landscaped drives and boundaries. Low cost residential areas are in clusters of small lots with very regular and repetitive roof patterns.
	* Emphasize that everyday observations assist in the recognition of buildings.
B. Highways	* Indicate that a low cost gravel road is identified on an aerial photograph by sharp turns, light gray tone, and very irregular edges. In front of farmhouses, a dark gray tone may occur where oil has been applied to keep down the dust.
	* Explain that bituminous roads have an intermediate gray tone. High quality bituminous roads may be distinguished from low quality roads by differences in width, edges, shoulders, and drainage. Low quality roads have irregular edges, almost no shoulders, and poor drainage ditches overgrown with brush.
	* State that concrete roads will be very light gray to almost white in tone, have sharp edges, and contain transverse lines of dark gray or black tone that indicate various joints in the pavement. On an old, well used concrete road, longitudinal oil smears will be visible on large-scale photographs.
C. Railroads	* Exhibit an aerial photograph showing a railroad.
	* Mention that the railroad is in direct contrast with the highway in alignment and in width. Point out the following about railroads:

Lesson 13 - The Highway Plan

OBJECTIVES

1. To introduce the component parts of the highway plan as designed in the New York State Department of Transportation
2. To understand the role of drawing in the finished plan

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. The Highway Plan	* Define the highway plan as a book of plans prepared by a design team to inform the contractor about how to build the highway.
A. Purpose	* Mention that every detail necessary to the construction of a highway is described in this set of plans, either by drawings or by notes.
B. Standards	* Explain that certain aspects of a highway design are standard and that this information is furnished on standard sheets. * Point out that since every highway varies in terrain, soil conditions, drainage, and right-of-way, standards for a complete design are impossible.
C. Divisions	* Emphasize that there are 16 divisions in a modern highway plan. In small projects or in special contracts some of the categories are unused or combined with another division.
II. Divisions of Plans	* Display the various divisions of the plan, using a large-scale set mounted on a frame. * Furnish the class with as many copies of the plan as possible and have the students form small groups around them.

22145

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Cover sheet	* Note that the cover sheet will vary with the project and the design engineer. In general, the following information will be on the cover sheet and on the next sheet or two.
1. Title of project	* Explain that the title of the highway is shown as either a construction or a reconstruction project and the following information always appears on the cover sheet: 1. Contract limits 2. Length of work in stations and in miles 3. Name of city, town, or county 4. Total number of sheets 5. Sheet number (1 on the cover sheet) 6. Contract number
2. Corner insert	* Mention that every sheet has a box insert in the upper right-hand corner with pertinent information concerning Federal aid numbers, sheet number, and the total number of sheets in the complete plan. * Note that the title is repeated in this box insert. * State that for the cover sheet only a note appears just below the box which indicates the type of construction and its length. Another note, just below the last one, indicates the listing of the standard sheets necessary for the contract. * Indicate that the date of the specifications used is also included.
3. Approval and recommendation	* Differentiate between the signature of the district engineer, who recommends the project for construction by his signature, and the approval by the chief engineer of the Department of Transportation.

22146

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Index sheet	* Explain that the index sheet is necessary when involved with a large set of plans.
C. Table of maintenance	* Describe the table of maintenance as a list of the portions of the contract showing the political entity that will maintain each section after the completion and acceptance of the contract.
D. Small-scale key map	* Point out the key map (scale usually 1 in. equals 200 ft.) and indicate that the following elements are shown by this map: 1. North arrow and scale 2. New centerline with stations 3. Base line with transit points and stations 4. Beginnings and endings of curves with stations 5. Equalities in horizontal alinement 6. Contract limits 7. A certain amount of existing topography 8. Property lines and property owners 9. Profile on a vertical scale of 1 in. = 20 ft. and on a horizontal scale of 1 in. = 200 ft.
E. Typical sections and general notes	* State that the typical sections and general notes describe completely each part of the new highway as it will be built. * Discuss the scales used in these sections. * Show how the typical section is defined between certain stations. * Explain how the typical section describes the items to be used in the construction.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	concrete boxes, arches, or large corrugated metal pipes are shown on the drainage structures sheet. * State that any special design involving manholes, catchbasins, and covers is also detailed here.
I. Miscellaneous details	* Mention that fencing, curbing, sidewalks, or retaining walls are shown under miscellaneous details. * Indicate that anything that is on the standard sheets will not be detailed again.
J. Roadside development	* Note that roadside development indicates the schedules for planting trees and bushes, seeding, clearing and grubbing and includes the following: 1. Location of plantings 2. Types of bushes and trees 3. Preparation by the landscape architect 4. Table of tree removals
K. Parking areas	* State that the design of the parking area sites with required quantities is shown and includes the following: 1. Drives 2. Guide railings 3. Seeding schedules
L. General large-scale plan	* Note that the large-scale plan (50 ft. for rural highways and 20 ft. for urban highways) is the nucleus of the highway design. * Mention that on large contracts two sheets are often used to cover the same area, one for drainage and one for layout. * Point out that the following important elements are shown on most combination layout and drainage sheets:

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

1. Base-line alinement with transit points and ties, with stationing and azimuths
2. New centerline alinement (marked as centerline of improvement), with stations and bearings or azimuths
3. Horizontal curves, complete with design data
4. Topography in its entirety
5. The new right-of-way line
6. Demolition items
7. North arrow and scale
8. Bench-mark location and elevation
9. Appropriation map numbers, together with the type of acquisition such as a temporary easement, permanent easement, fee taking with or without the right of access
10. Limit of grading
11. Limits of work at the beginning and at the end and also on the sidelines
12. Drainage notes
13. Invert elevations at all drainage structures
14. Culvert pipe flow
15. Stream relocations
16. Special ditch sections
17. Equalities
18. Fencing

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

19. Utility relocations

20. Temporary work

M. Profiles

* Note that on most contracts the profile is placed in the lower portion of the design plan. With arterial work the tendency is to place the profile in a special section.

* Point out that there is much design information on the profile sheets and includes the following:

1. Datum
2. Scales
3. Stationing
4. Vertical curvature and data
5. Percentage of grade in new line
6. Drainage structures in elevation view
7. Passing sight distance and safe stopping distance
8. Equalities

* State that the cross-section sheets used to design the project are not part of the contract.

N. Lighting and traffic control signals

* Emphasize that lighting and traffic control information is listed only when required for a given project. This occurs mostly on arterial highways.

* Note that a special set of large-scale plans are drawn for lighting, but the alinement is shown only with pavement edges, cross streets, and centerlines.

* Discuss the symbols used on the lighting sheets.

* Explain the lighting detail sheet and show how the conduit and pull boxes are indicated.

* State that any design for traffic signals is described on its own sheet.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

O. Bridges

* Show plans which include a bridge and state that the order of sheets is:

1. Plan views and elevations
2. Rounded and neat quantities
3. Approach sections
4. Footings, abutments, and piers
5. Superstructure
6. Bar lists of reinforcing steel
7. General notes

P. Standard sheets

* Discuss some of the more common standard sheets used in highway design and explain how the draftsman often has to make certain changes in a standard sheet. Show how the sheets are filed in a standard sheet book, one for roadway and one for bridges.

QUESTIONS FOR REVIEW

1. Why is it difficult to standardize any more of the highway plan than is done now?
2. List five items that appear on the cover of highway plans.
3. What is the table of maintenance?
4. Describe the key map as used on highway plans.
5. Are the typical sections of a highway plan scaled drawings?
6. Why is a retaining wall drawn in detail while a drop inlet is not?
7. What can be done to ease the concentration of details on a contract plan sheet of a very complex urban design?
8. Why are the dimensions on the bridge plans in feet and inches?

ASSIGNMENT

Furnish students with a contract plan (200-ft. scale plan and profile) and have them draw on a 50-ft. scale a 15-station portion of the plan. Note that the work is to be done in pencil on vellum so it can be checked as an overlay on the original 50-ft. contract plan.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
4. Design staff	* Point out the signatures of the engineers who worked on the individual sheets. Each sheet will have at least three signatures in the bottom left-hand corner.
5. Location maps	* Indicate that the map of the State of New York on the cover sheet is divided into the 10 geographical districts. In the district involved there is a circle denoting the rough location of the contract. * Call attention to the larger scale map (usually a tracing of an U.S.G.S. topographic map of the area) with the new highway shown as a very heavy line. This map also shows the contract limits of the project.
6. Design data	* Explain the meaning of the following information found in the design data box: 1. The design classification of the highway 2. The projected traffic count (20 years usually) showing the design hour traffic count and the annual average daily traffic count
7. Project numbers	* Indicate that the project number appears outside of the border in four places on the first sheet, and outside of the border in the upper right-hand corner on subsequent sheets. * State that the first number is the year the contract was let. * Explain the following: 1. F.A.R.C. 2. F.G.R.C. 3. R.C. 4. F.A.C. 5. F.A.S.H. 6. F.A.L.D. 7. F.A.S.S.

22147

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Explain that specialized conditions are shown and include the following typical sections: 1. Ditch 2. Special ditch 3. Interceptor ditch 4. Gutter 5. Rock 6. Bank 7. Classification of embankment in a fill
F. Miscellaneous tables	* Mention that miscellaneous tables furnish locations and quantities. * Exhibit the various tables used in the different contracts. * Explain that there is no precise pattern as to the order of listings or distribution of tables but might include any of the following: 1. Lengths 2. Drainage structures 3. Bench marks 4. Driveways 5. Guide railings 6. Trench, culvert and bridge excavation summary 7. Unclassified excavation 8. Earthwork summary 9. Items 10. Curve data 11. Old pavement removals 12. Guide posts 13. Fencing 14. Paved shoulders 15. Right-of-way markers 16. Curbs 17. Signs 18. Concrete or asphalt concrete gutters
G. Delineator details	* Note that a small-scale plan of the entire contract is shown with the necessary information as to type and location of the delineators used.
H. Drainage structures	* Emphasize that the detail and quantities of large culvert structures consisting of multiplate arches,

HIGHWAY DRAWING

Glossary of Abbreviations

Elev. or El.	= Elevation
E.P.	= Edge of pavement
Eq.	= Equality
E.S.	= End section
Ext.	= External
Fd.	= Foundation
Fr.Ho.	= Frame house
G.	= Gas
G.P.	= Guy pole
G.S.B.	= Gas service box (house line)
G.V.	= Gas valve (main line)
H.I.	= Height of instrument
Ho.	= House
H.P.G.	= High pressure gas
H.S.D.	= Headlight sight distance
H.W.	= Headwall
Hyd.	= Hydrant
Inv.	= Invert
I.P.	= Iron pin or iron pipe
L	= Length
L.P.	= Light pole
L.P.G.	= Low pressure gas
M	= Measured distance
M.H.	= Manhole
M.H.W.	= Mean high water
Mon.	= Monument
N & R	= Nail and red
N & W	= Nail and washer
O.C.M.P.	= Oblate corrugated metal pipe
O.H.W.	= Ordinary high water
O.S.	= Original surface
Pav't	= Pavement
P.C.	= Point of curve
P.I.	Point of intersection
P_L	Property line
P.M.	Procedure manual
P.O.L.	Point on line
Por.	Porch
P.O.T.	Point on tangent
P.P.	Power pole
P.S.D.	Passing sight distance
P.T.	Point of tangent
P.V.I.	Point of vertical intersection
R	Radius
R.C.P.	Reinforced concrete pipe
Rd.	Road
R.O.W.	Right of way line
RR	Railroad
S.C.	Point of spiral to curve
SH	State highway

22166

HIGHWAY DRAWING

Spk.	= Spike
S.S.	= Shoulder stabilization
S.S.C.	= Same slope continues
S.S.D.	= Stopping sight distance
S.T.	= Point of spiral to tange
St.	= Street
Stk.	= Stake
Sto.Ho.	= Stone house
Sty.	= Story
SW.	= Sidewalk
T	= Tangent (ts = spiral; Tc = compound)
T.B.	= Top of bank (stream)
T.C.	= Top of curb
Tel.P.	= Telephone or telegraph pole

Glossary of Abbreviations

T.G. = Top of grate

T.H.W. = Top of headwall

T.L. = Tree line

T.O. = Top of opening

ent T.P. = Turning point

T.Pt. = Tie point

T.S. = Point of tangent to spiral

V.C. = Vertical curve

V.C.P. = Vitrified clay pipe

W = Water

W.S.B. = Water service box (house line)

W.V. = Water valve (main line)

W.W. = Wingwall

° ' " = Degrees, minutes, & seconds such as 6°26'33"

22167

FINAL EXAMINATION

Final Examination Part I — True or False Statements

INSTRUCTIONS: In the space provided, write the letter T if a statement is true and F if the statement is false.

F 1. The loop spring type of bow instrument is popular because it is easier to hold in one hand.

T 2. When drawing plans for a highway project, the architect's scale is used on many aspects of bridge design.

T 3. A pencil soft enough not to smudge and hard enough not to cut grooves in the paper is used in higheway drawing.

F 4. If the blades of a ruling pen are pointed, the ink will tend to flow too freely.

T 5. A map scale of 1:62,500 is actually 1 in. = 1 mi.

F 6. A closed contour line on a map indicates a summit.

T 7. The horizontal distance between contour lines is inversely proportional to the slope.

F 8. In lettering, the letters N, Z, V, and Y belong to the same group.

T 9. Soapstone is used to place a slick, smooth finish on damaged areas of tracing cloth.

T 10. In linear miles 1 degree of latitude is approximately equal to 1 degree of longitude at the Equator only.

F 11. On a U.S.G.S. map a number placed at a highway intersection is an index number for location.

F 12. If one has an excellent memory, he may enter field information in the notebook at a later time and perhaps at a more convenient place.

T 13. A cross-section is a profile made on a line at right angles to a base line.

F 14. The cover sheet of a set of highway plans consists only of administrative information and the title of the project.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	1. Very long radius horizontal curves 2. Follow the natural topography more than highways 3. Seldom show a connection to a building cluster 4. Cuts and fills more frequent and larger than highways
D. Fields	* Mention that individual fields are easily recognized on aerial photographs and that it is possible to identify general types of crops by the gray tone, height, and texture conditions as follows: 1. Green crops photograph dark gray to almost black. 2. Stubble fields will be light gray in tone. 3. Pasture land is irregular in tone, somewhat splotchy, and contains trails.
E. Natural features	* Point out that rivers, streams, creeks, and gullies are readily visible with the major streams showing a very definite shape and a gray tone. * Indicate that lakes, ponds, swamps, and marshes are recognized by shape, gray tone, and texture. Bodies of water are very smooth in appearance while swamps show irregular texture of brush. * Mention that general topographic shapes and surface configurations may be easily recognized. Basins, plains, hills, valleys, ridges, and mountains are spotted by shape and position with respect to the surroundings. * Stress that natural material types are recognized by studying the geology of the area and using comparable geologic maps. * Explain that trees and woods are easily identifiable and point out that

22157

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	often the shadows assist in the recognition of tree types.
	* State that much drainage information is found on aerial photographs as well as the characteristics of watersheds.
	* Note that erosion characteristics may help to identify soil types.
	* Point out that a light gray tone in the aerial photograph indicates coarse textured, well-drained soils while a medium gray tone indicates heavy textured clays and silty clays. Organic soils photograph dark gray and muck soils show almost black.
F. Controls	* Establish that there are certain features which could control a highway alinement—airports, factory buildings, and educational institutions—that can be detected if a similar situation or shape has been recognized before.
	* Point out a cemetery on an aerial photograph (an important highway control) and indicate that it may be identified by landscaping features, winding or closely spaced road systems, and the white dots that represent the gravemarkers.
III. Photogrammetry	* Indicate that photogrammetry is the science of obtaining reliable measurements by means of aerial photographs.
	* Mention that the science of photogrammetry combined with techniques of electronic surveying makes it possible to establish the position and elevation of any point on the earth's surface and to compile accurate topographic maps without actually setting foot on the ground.
A. Characteristics	* Explain that the aerial photograph is a perspective projection, somewhat like the ordinary photograph, but that

22158

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	a photogrammetric model is made by taking the same picture from a camera in two different positions. (Ref. D, pp. 847-849)
	* Compare this operation with that of the human eye and describe the duplication of natural binocular vision as stereovision.
	* Explain that the three-dimensional impression constructed by the mind is a spatial model. (Ref. D, p. 843)
B. Scales	* State that the scale of an aerial photograph is expressed either as a representative fraction or as a ratio between 1 in. on the photograph and a specific distance on the ground. (Ref. D, pp. 874-876)
	* Indicate that topographic maps are made to any scale desired.
	* Show some aerial photographs using the common scales of 1 in. equals 440 ft., 1 in. equals 660 ft., or 1 in. equals 1,320 ft. If possible, use aerial photographs of the same area.
	* Demonstrate the computation of a scale by using a sketch with similar triangles. (Ref. D, p. 874)
	* Determine the flight altitude necessary to obtain a photograph at the desired scale. (Ref. D, pp. 877-878)
	* Ascertain the coverage of aerial photographs by computing the net area covered by a single photograph. Use a 60-percent overlap in the line of flight and a 30 to 50-percent overlap between the lines of flight in the computations. (Ref. D, pp. 878-879)
C. Accuracy	* Indicate that horizontal accuracy is established at 1 percent for all

22159

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Indicate that since the stereoplotter is able to perform the above operations in one continuous process, the instrument is the basis of most topographic maps made from aerial photographs. (Ref. D, pp. 911-912)
E. Use of map data	* Explain that the construction of profile and cross-sectional data is easily done from a contour map.
	* Note that improved models of digital computers can be connected to the stereoplotter and all the information derived from the aerial photograph can be computed and filed electronically.
IV. The Digital Computer	* Describe the digital computer as one of the most important tools of the modern highway engineer.
	* Explain that the engineer performs calculations on the computer for the basic purpose of making decisions and communicating information to others.
	* Note that the engineer often has routine problems that can be performed by a computer. This relieves him of a time-consuming job essentially mechanical in nature. But the engineer still remains fully responsible for contributing the necessary knowledge of engineering and mathematics, experience, and judgment required to solve the problems at hand.
A. The digital computer as a hypothetical mechanical man	* Compare the digital computer to the hypothetical mechanical man in that the abilities of the mechanical man would be limited to reading simple instructions and data, making very limited decisions based on simple rules, and writing down answers.
	* Indicate that since the mechanical man lacks knowledge in engineering and mathematics, that since he cannot exercise judgment or express emotion,

22161

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	he stands ready to do only what the engineer instructs him to do.
B. Operation	* Point out that the greatest problem is that of efficient communication between the engineer and the mechanical man. * State that the digital computer is a machine which can perform calculations, make simple decisions at high speed, and memorize a list of detailed instructions. * Describe the IBM 1620 computer, which is used by the Department of Transportation in New York State. * Exhibit photographs of the different units of the computer and explain briefly the function of each individual machine. * Explain that the steps in machine computation are: 1. Problem formulation 2. Problem statement 3. Input and output 4. Ranges and precision 5. Programing or flow charting 6. Error checks 7. Summary
C. Capabilities	* List and describe the basic capacity of the digital computer as being able to: 1. Follow automatically a set of stored instructions expressed in its own language 2. Make simple logical decisions and automatically alter a sequence of operations 3. Perform simple arithmetic operations such as adding, subtracting, multiplying and dividing at high speed

22162

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
D. Automatic plotters	* Describe the following types of plotters used with the digital computers: 1. On-line plotter 2. Off-line plotter 3. Point plotter 4. Line plotter 5. Cathode ray tube plotter
E. Highway engineering applications	* State that due to the cost of programing, the computer is used to its best advantage on problems which occur repetitively. * List the following as the geometric calculations which are handled with great efficiency on the digital computer: 1. Survey calculations 2. Horizontal alinements 3. Vertical profiles 4. Sight distances 5. Right-of-way takings 6. Curves and spirals 7. Superelevations 8. Interchange geometrics 9. Bridge geometrics * Establish that the machine cannot design in the sense of furnishing the concept for a solution of the problem. It cannot use judgment or experience. * Stress that the computer can evaluate hundreds of correct solutions for a given problem, thus affording an economic optimization of location and design solutions. * Point out that in the design units of this course, more information will be given on the use of the computer for actual design work.

QUESTIONS FOR REVIEW

1. What is photogrammetry?
2. Explain the use of the stereoscope.
3. Describe how various types of highways are identified on an aerial photograph.
4. How can a body of water be differentiated from a swamp?
5. How is the representative fraction of an aerial photograph noted?
6. Explain the circumstances under which the digital computer works to the best advantage of a design office.

ASSIGNMENT

Announce that the final examination will be given at the next class.

INSTRUCTOR'S NOTES

22165

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	grid lines and control points and 2 1/2 percent for all planimetric features.
	* State that vertical accuracy is established so that 90 percent of the map has an error no greater than one-half of the contour interval. The remaining 10 percent of the map will have an error no greater than the contour interval.
D. Procedures	* Stress that the aerial photographs are used in various ways to produce different information for the engineer.
1. Analytical	* Explain how the stereocomparator is used for measuring linear distances on the aerial photograph. (Ref. D, pp. 911-926)
	* Note that this is also called the "digital approach", since the measured distances can be fed into a digital computer and stored for use in making a map.
2. Graphical	* State that by using the stereoplotter the figures from the aerial photographs can be stored in lines or shapes (cross-sections or contour). This is also called the analog approach.
	* Describe the stereoplotter and discuss the following: 1. The projection system 2. The viewing system 3. The measuring system 4. The plotting system
	* Point out that in compiling a topographic map from stereoscopic photographs the stereoplotter: 1. Compensates for tilt in the photograph 2. Measures elevation and delineates contour 3. Plots the compiled information onto the map manuscript

TRAINING COURSE FOR

RECEPTIONISTS

The material in this guide is presented in the form of suggestions. Every student participating in this program will be different in regard to education, experience, and ability. The instructor must, therefore, adjust and adapt the suggestions in this guide to the needs of individual students.

The first step in insuring this adjustment is to secure as much information as possible about each new student. This can be accomplished through study of the pre-enrollment information gathered by the Center counselors. The second step is to keep up to date on the progress of each student through the regular use of the information prepared by Individual Program Control (IPC). With this information on hand the instructor can effectively adapt specific objectives, teaching methods, and time alloted to each aspect of the training, directly to the student's needs.

This guide will aid the instructor in accomplishing part of his job. It will provide performance objectives, suggest time allotments, unit outlines, and supplemental teaching aids. Only the instructor, however, can combine these factors with a knowledge of each individual student.

Course Objectives:

The receptionist program at Gila River Career Center is designed to:

1. develop in the student an awareness of the importance of office work and of the career opportunities which it offers.

2. develop in the student an understanding of the place and purpose of the office in general, and the receptionist in particular, in the typical business organization.

3. develop a job-centered approach to development of business-like work habits and attitudes and effective human relations.

4. prepare the student to perform the fundamental tasks commonly required of all beginning office workers.

5. prepare the student to perform the technical tasks commonly expected of the receptionist.

__T__ 15. Along the line of survey, aerial photographs overlap each other by 60 percent.

__T__ 16. Cross-sections for a preliminary survey are plotted in pencil and then inked.

__F__ 17. A true north and magnetic north symbol must have a date on the arrow.

__T__ 18. When drawing concentric circles, the smallest one is drawn first.

__T__ 19. An Arkansas knife piece is used to sharpen a ruling pen.

__F__ 20. The protractor is divided into degrees, minutes, and seconds.

Final Examination Part II — Fill-In Statements

INSTRUCTIONS: Complete the following statements.

1. When shading a symbol, the source of light is assumed to be coming from above and to the LEFT of the object at an angle of 45°.

2. If an observer wishes to view aerial photographs in three dimensions, he should use a STEREOSCOPE.

3. The process of determining the elevations of points at measured intervals along a fixed line is called PROFILE leveling.

4. The method of locating a certain point on the earth may be done by using the COORDINATE system.

5. The U.S.G.S. generally uses the POLYCONIC projection for making their topographic maps.

6. The ozalid process of duplicating requires AMMONIA vapor in the presence of light.

7. Prominent natural land features are lettered in UPRIGHT capitals.

8. When filling a ruling pen, never place more than ½-in. of ink in the pen.

9. The engineer's triangular scale has THREE calibrated edges.

10. The engineer's triangular scale has SIX available scales.

11. The first step in making a topographic map is the plotting of HORIZONTAL control.

12. The contour interval is the VERTICAL distance between contours.

13. On a topographic map the FIFTH contour is always drawn heavier.

14. Various types of projections used to achieve one certain purpose are called a (an) CONFORMAL.

15. The scale of a 7½-minute U.S.G.S. map is 1:24,000.

Final Examination Part III — Matching

INSTRUCTIONS: Write in the space provided the number of the expression in Column B which is best suited to the expression in Column A.

	Column A	Column B
4	Ruling Pen	1. Ebonized hardwood
8	Economic operation	2. Finished drawing
11	Arterial highway plan	3. Quarter scale
18	Copying device	4. Reflection method
3	Architect's scale	5. French curve
13	Ampersand	6. 1/F = S/L
20	Freehand lines	7. 1:62,500
12	W	8. Blueprinting process
5	Non circular	9. H.I.
1	T-square	10. Subdivision names
16	Tangent offset method	11. 20-ft. scale
10	Upright capital letters	12. Water
2	2H pencil	13. &
9	Height of instrument	14. Hydrographic names
6	Equation of scale	15. Wind
		16. Horizontal control
		17. Bench mark
		18. Pantograph
		19. Ozalid process
		20. Contour lines

Final Examination Part IV — Multiple Choice

INSTRUCTIONS: Place an X in the space next to the choice which most accurately completes the statement. Read all possible answers.

1. The revolving triangle method of drawing lines enables one to draw:

   _____ (a) A line parallel to another line

   _____ (b) A line at an angle with another line

   _____ (c) A line bisecting another line

   __X__ (d) A line perpendicular to another line

2. Using a T-square and a 45° and a 30°-60° triangle, a student may draw lines at any angle which is a multiple of:

   _____ (a) 5°

   _____ (b) 10°

   __X__ (c) 15°

   _____ (d) 20°

3. The heaviest lines in any drawing are:

   _____ (a) Construction lines

   _____ (b) Dimension lines

   __X__ (c) Object lines

   _____ (d) Hidden lines

4. A drawing pen is checked for dullness by:

   _____ (a) Using a micrometer

   __X__ (b) The reflection method

   _____ (c) Cutting paper with one blade

   _____ (d) Running blade across fingertips

5. On a topographic map a canal would be classified as:

_____ (a) Culture

__X__ (b) Hydrography

_____ (c) Relief

_____ (d) Vegetation

6. When the scale of a topographic map is 1 in. equals 2000 ft. the representative fraction is:

_____ (a) 1:62,500

__X__ (b) 1:24,000

_____ (c) 1:2,400

_____ (d) 1:31,680

7. The most likely contour interval on a large-scale topographic map of flat country would be:

__X__ (a) 2 ft.

_____ (b) 10 ft.

_____ (c) 20 ft.

_____ (d) 100 ft.

8. The type of lettering most often used in highway drawing is:

_____ (a) Modern roman

__X__ (b) Commercial gothic

_____ (c) Old English

_____ (d) Old roman

9. The first item inked on a tracing is:

_____ (a) Straight horizontal lines

__X__ (b) Circles

_____ (c) Cross-hatching

_____ (d) Lettering

10. The projection used for a U.S.G.S. topographic map is:

_____ (a) Mercator

__X__ (b) Polyconic

_____ (c) Gnomonic

_____ (d) Stereographic

11. The shape of a U.S.G.S. topographic map with a scale of 1:24,000, covering an area of 0°7'30" of latitude and of longitude, is:

_____ (a) Square

__X__ (b) Rectangular

_____ (c) Parallelogram

_____ (d) Rhombic

12. The planimetric map shows only:

_____ (a) Drainage

_____ (b) Culture

__X__ (c) Drainage and culture

_____ (d) Drainage, culture, and relief

13. The topography, referenced by a field surveyed base line, is plotted by using:

_____ (a) A protractor

__X__ (b) A linear plotter

_____ (c) Tangent offsets

_____ (d) Perpendicular lines to the base line

14. The rodreadings of the level survey are plotted on the cross-sections after the height of instrument has been:

_____ (a) Added

__X__ (b) Subtracted

_____ (c) Divided

_____ (d) Multiplied

22174

15. The scale for the general highway plan for a rural highway is usually made at:

_____ (a) 1 in. = 10 ft.

_____ (b) 1 in. = 20 ft.

__X__ (c) 1 in. = 50 ft.

_____ (d) 1 in. = 100 ft.

16. The size ratio of the capital "W" to the capital "M" is:

_____ (a) 8 to 7

_____ (b) 8 to 6

__X__ (c) 8 to 6-1/2

_____ (d) 8 to 5-1/2

17. An item not classified as special equipment is a:

_____ (a) Beam compass

_____ (b) Contour pen

_____ (c) Railroad pen

__X__ (d) Erasing shield

18. When the ink refuses to flow from a ruling pen:

__X__ (a) Pinch the blades

_____ (b) Shake the pen

_____ (c) Tap the pen

_____ (d) Place more ink in the pen

19. In the alphabet of lines, the finest line is a:

__X__ (a) Construction line

_____ (b) Object line

_____ (c) Dimension line

_____ (d) Hidden line

22175

20. The most exacting item in drawing is:

_____ (a) Detail

__X__ (b) Horizontal control

_____ (c) Contour

_____ (d) Symbols

This booklet is published primarily for use in the schools of New York State, and free copies are available to New York State school personnel when ordered through a school administrator from the Publications Distribution Unit, State Education Building, Albany, New York 12224.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
II. Course Description	Explain that this course introduces students to highway planning as a prerequisite to highway location and design in rural areas. Stress the importance of planning even for sparsely developed areas because of the effect of highway location and design on area development. Also tell the students about the new concept of total transportation and the advanced techniques required for the State's complex urban areas.
A. Title and resume of each lesson	Explain briefly the subject material to be covered in each of the 15 lessons of this unit.
1. Introduction to the course	Lesson 1 deals with the growing awareness of the need for coordinated planning of all transportation facilities and the important role played by highways. This lesson also covers Federal aid requirements, Federal and New York State laws, and the advantages to the highway technician of learning about the planning process.
2. Fundamentals of highway planning	Lesson 2 presents factors which determine the need for a new road, its location, and the benefits to be gained. This lesson also discusses the relationship of highway planning to other types of planning by many different organizations.
3. Highway agencies and systems in New York State	Lesson 3 describes the highway agencies of the State, and of the county, town, city, and other subdivisions. The systems of highways in the State are also described, as well as the relationships among all types of highways and the sources of finances for them.
4. Road inventory and field scoring	Lesson 4 covers taking inventory of existing roads, including complete descriptions, and the field scoring of

22186

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	roads. This scoring shows the adequacy of a road in meeting required conditions of maintenance and volume of traffic.
5. Mapping as a planning tool	Lesson 5 deals with the types of maps available and the features of each. Uses of aerial photographs, United States Geological Survey maps, and other maps are also described in this lesson.
6. Traffic studies	Lesson 6 covers volume counts by machine and by hand, origin and destination surveys, classification counts, turning counts, and uses of traffic surveys.
7. Traffic analysis	Lesson 7 presents methods of making a traffic analysis, using volume characteristics and vehicle classifications. Also covered are the analysis of travel characteristics and the use of traffic analysis to determine highway improvements and new locations.
8. Traffic forecasting	Lesson 8 deals with traffic forecasting and trends in traffic volume. This lesson stresses highway planning for maximum economy.
9. Economic analysis	Lesson 9 presents the major steps in making an economic analysis for highway planning. Costs for alternative plans, and costs due to social and other factors are also analyzed.
10. Geometrics and highway standards	Lesson 10 is concerned with design standards and how these standards vary with traffic volume, terrain features, and type of area. This lesson also describes New York State geometric standards and their applicability to different types of highways.
11. Route location	Lesson 11 deals with the planning of highway routes and corridors. It also explains the basic differences between planning and preliminary engineering.

22187

FOREWORD

This teacher's guide, *Elements of Highway Planning*, is one of a series in the Highway Technicians Program. It was produced by the New York State Education Department with the help of the New York State Department of Transportation (formerly the Department of Public Works).

The Department of Transportation had requested the program originally, and the Education Department then produced the first editions of Units I through V. In 1967 the DOT (under the leadership of Philip E. Hagerty, Deputy Assistant Commissioner for Manpower and Employee Relations) called for an increased effort to complete the program, and to update any previously published guides needing updating. As a result, the part-time services of several DOT engineers were made available to do the writing required, and to assist the Education Department in producing the guides.

John L. DeLee, now Principal Civil Engineer in the Bureau of Highway Planning of the Department of Transportation, initiated and carried on the original planning of the content for the program. In this planning he was aided by other personnel of the DOT district offices. Mr. DeLee also acted as liaison with the Bureau of Occupational Extension and Industrial Services (later absorbed into the Bureau of Trade and Technical Education) in the Education Department.

Edward Umiker, now Associate Civil Engineer in the Buffalo District Office of DOT, and Ralph Fimmano, Senior Civil Engineer in the Utica District Office, collaborated with Mr. DeLee and the Education Department in developing outlines for the courses in the program.

Elements of Highway Planning, (which is a revision of the first edition of Unit IV, entitled *Preliminary Highway Planning*) was written by Jacob Mende, Assistant to the Chief Engineer of DOT. John C. Kacharian, Chief Engineer, Post Engineer's Office, Watervliet Arsenal, made revisions in some of the material. E. Noah Gould, Associate in the Bureau of Continuing Curriculum, supervised the writing and revising, and prepared the material for publication.

The Bureau of Continuing Curriculum Development gratefully acknowledges the parts played by each of the individuals and organizations mentioned above in producing this guide.

CONTENT OUTLINE

C. Required student equipment

1. Textbooks

2. Looseleaf notebook

D. Course prerequisites

E. Purpose of course

TEACHING POINTS AND TECHNIQUES

Write the author, title, publisher, and copyright date on the chalkboard for each of the basic textbooks for the course, Refs. A and F.

State that it is advisable for each student to order these two books. Mention that they are the basic textbooks to be used throughout the course, and that they can be reference books for many years.

Ask the students to sign on a sheet of paper so you can have a class list.

Tell them that the course varies somewhat from the textbooks.

Suggest that students keep a looseleaf notebook for the course. You might want to mimeograph sheets showing the content outline to facilitate notetaking. Many of the ideas to be developed in the course are not readily found in books and the notes will be valuable for future reference.

State that Units I, II, and III of the Program for Highway Technicians are preferred prerequisites for this course.

Summarize this introduction by explaining the aims of the course:

1. To upgrade the highway technician who works on survey, design, construction, maintenance, traffic, or some other phase of highway work

2. To show the relationships among the technician's job, the elements of highway planning, and the science of transportation planning

3. To convey to the highway technician useful factual data and a broad perspective on highways as a development force

22185

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
12. Safety	Lesson 12 covers the Federal and State highway safety programs. It discusses standard safety measures, use of highway signs and signals, and the Department of Transportation Safety Crusade.
13. Highway law	Lesson 13 deals with highway law, the lawmaking process as it applies to Department of Transportation bills, and the channeling of local bills. Several articles in the highway law which affect the day-to-day workings of the Department are also explained in this lesson.
14. Highway financing	Lesson 14 describes various methods of financing highway construction. It discusses free roads and toll roads, and the taxes, fees, and bond issues used for construction.
15. Introduction to urban transportation planning	Lesson 15 deals with the new science of transportation planning for urban areas. It includes the use of models to determine travel flow and the fundamentals of urban transportation planning.
III. Summary	Briefly summarize the importance of highway planning in providing safe and economical highways that meet the broad needs of an area.

QUESTIONS FOR REVIEW

1. What benefit will a highway technician receive from a knowledge of highway planning?

2. What is the difference between highway planning and transportation planning?

3. Why is a different study technique required for planning a highway for a large urban area as compared to a small rural area?

4. In highway planning what factors should be considered besides location and type of highway?

ASSIGNMENT

1. Read page 411 in Ref. A.

UNIT I (14.0406-01)

OCCUPATIONAL ORIENTATION

Performance Objectives:

Upon completion of this unit the student will be able to describe orally the general purpose and organization of business. She will be able, as determined by instructor observation, to demonstrate good interpersonal relations with other class members and good organization of a work station.

The student will be able to demonstrate in a role playing, or other simulated situation, the proper dress and grooming for an office worker and correct techniques and good manners. She will be able to score 80% on an objective test covering the responsibilities of a receptionist.

Unit Outline:

A. Review of Modern Business Enterprise

   1. Methods of organization

   2. Purposes of business

B. Types of Offices and Opportunities for Office Workers

C. What Business Expects of Office Workers

   1. General expectations

   2. Appropriate attire

   3. Posture and figure control

   4. Complection and health

   5. Personal hygiene

D. Office Techniques of Etiquette

   1. Basic good manners

   2. Application of social graces to office situations

   3. Some special problems that occur

E. Interpersonal Relations

   1. Role of motive and emotion

   2. The office worker's role in business-human relations activities

2. Read Ref. C, including all the sections mentioned in the reference.

3. Read Section 134 in Ref. D.

4. Read section 402 in Ref. E. Write in 100 to 200 words your opinion of the Federal role in State highway activities.

5. Read pages 2-3 to 2-6 in Ref. F.

22189

OBJECTIVES

1. To acquaint the students with the basic concept of highway planning as a science
2. To show the relationship between highway planning and comprehensive planning for an area

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Fundamentals	Explain that the science of highway planning can be divided into two parts, regardless of whether it is applied to a small area or a much bigger metropolitan area.
A. Is a new road necessary?	State that we cannot answer this question in only one way, even for a simple project like a village bypass. Many studies are needed, regardless of the size of the project.
1. Inventory of roads	Tell the students that in good highway planning we must take stock of existing roads, whether we are dealing with a

22190

MESSAGE TO THE INSTRUCTOR

The rapid expansion in the building of state and Federal highways has caused a serious shortage of qualified highway technicians and engineers. The New York State Department of Transportation and the State Education Department have collaborated in the Highway Technicians Program to overcome this shortage.

This program is expected to provide additional technicians and engineers by upgrading people employed in technician jobs. This teacher's guide, *Elements of Highway Planning*, and the others in the program are intended to improve the skills and technical knowledge of those who plan, design, construct, operate, and maintain the State highways and canals.

Local boards of education and other sponsors of adult education programs are being encouraged to offer the courses in this program as part of occupational education. Besides attracting students from the Department of Transportation these classes will also draw employees of the public works departments of counties, cities, and towns, and of construction contractors.

Enough subject matter has been included in each lesson of this guide for about 2-1/2 hours of classroom instruction. The total length of the course, however, may be adjusted to fit the experience and education of enrollees.

BERTON P. PLUMMER, *Chief*
Bureau of Trade and
Technical Education

JOHN E. WHITCRAFT, *Director*
Division of Occupational Education

OBJECTIVES

1. To provide a general description of the course
2. To acquaint the students with the changing role of highway planning in shaping the world we live in
3. To explain the value of each phase of this training
4. To acquaint the students with the program of the New York State Department of Transportation

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Introduction	Print the name of the course and your name on the chalkboard. Give the students a brief description of your background.
A. Purpose of course	Explain that the course is given to improve the knowledge of technicians in highway planning and to help them advance in their jobs in highway design, construction, and maintenance.
B. Introduction of class members	Have each student introduce himself to the class, volunteering information about himself, such as name, occupation, and where employed.

NATIONAL BUREAU OF S

ON TEST CHART
TANDARDS-1963-A

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	small two-lane approach or a complex network of highways. The capital investment in existing roads is too high to make changes without very good reason.
2. Studies of traffic volume and classification of roads	Explain that highways are built to move people and goods. We must know the quantities moved and the physical condition of the roads before we can decide what improvements are needed.
3. Traffic analysis	State that raw data alone, (from the traffic studies) do not give us the answers we need. We must convert traffic counts to *average annual daily traffic (AADT)* and *design-hour (DH)* figures.
4. Traffic forecasting	Tell the students that in forecasting we must look 20 years ahead. We must do this to protect the public investment and to assure that a new road will meet future needs.
5. Geometrics	Show that determining the need for a new road is an orderly procedure. Determining this need will not only resolve the question of how many lanes are needed for 20 years ahead, but will also show that only a certain number of lanes are available on the existing location.
	Explain that control of access doubles or more than doubles the capacity of a highway. We must not leave out control of access without a very good reason.
B. Where should a new road be located?	State that before we decide we need a new road, we must first study the possibility of improving the existing road.
	Tell the students that except near very small cities and villages, most of the traffic in a given area has destinations in and around big population centers. Therefore, a bypass around a big popu-

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	lation center may not give the needed service.
1. Mapping	State that maps are another form of facilities inventory and we need them to show the geographical relationships of the roads and other facilities in an area we are studying.
2. Origin and destination (O&D) studies	Explain that figures for volume of traffic can show only overloads, but an O&D study can show whether traffic can be diverted from overloaded facilities.
3. Economic analysis	Inform the students that for good highway planning we must consider all feasible alternates and compare their costs and benefits. The consideration of benefits must include non-economic benefits, which cannot be measured in dollars.
	Point out that in an economic analysis we first determine from the O&D data whether or not a completely new facility is justified. If it is justified,we continue the economic analysis and evaluate alternate new facilities.
	Tell the students this procedure is similar to the concept of highway design in which two or more lines are compared for costs.
4. Route location	State that in the highway planning study we have now established the most desirable *corridor* from a cost and community service point of view. The design process now takes over to determine the best location for the highway within the selected corridor.
	Explain that the traffic and economic studies will establish the best *locations* and *types* of interchanges needed for the traffic conditions forecast. But specifying the location and type of an interchange does not constitute a design.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
II. The Relation of Highway Planning to Other Types of Planning	Explain that *planning* is such a general term, and there are so many kinds of planning that the meaning of *highway planning* tends to be vague.
A. Community planning	Tell the students that almost every city, town, village, and county has a planning organization or is forming one.
1. Planning board	State that a planning board is usually either an executive or an advisory group. Ordinarily none of its members are professional planners.
2. Planning staff	Show by an organization chart that a planning staff is usually no more than a staff arm to a planning board, or to a local government official.
a. Duties	Explain that the job of a planning staff is to prepare plans for its community. Also explain that local planning staffs are a valuable source of information about cities, villages, etc.
b. Coordination	Tell the students that it is to the advantage of the Department of Transportation to coordinate State plans with local plans for highway improvements. Show how knowledge about local plans will help the DOT in planning and development.
	Remind the students that highway planning is only one part of comprehensive planning, and that local planners are also concerned about schools, parks, public utilities, and other elements of community development.
B. Regional planning	Mention that sometimes it is in the public interest to make *one* plan for a broad geographical area, which might include several cities, villages, towns, and counties. The agency which plans for such a broad area is either public or quasi-public. The DOT will find that sometimes its plans for a highway must be modified to fit in with a regional plan.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. By a public agency	Explain to the students that a public agency like the Nassau-Suffolk Regional Planning Board might achieve greater public benefit by planning for a larger area than the DOT is planning for. For example, the Planning Board might bring a badly needed park to an area, where the DOT was planning only a by-pass.
2. By a quasi-public agency	Point out that a quasi-public agency like the Port of New York Authority has direct influence over large areas of the State and over areas which go beyond State boundaries. It is extremely important to coordinate State highway plans with Authority plans.
III. Summary	Briefly summarize the fundamentals of highway planning. Point out that two basic questions are posed: (1) Is a new road necessary? (2) Where should it be located? Emphasize how vital it is to coordinate State planning with the planning of other governmental agencies and groups. Briefly mention the scope of the next lesson.

QUESTIONS FOR REVIEW

1. What two questions should be answered by a highway planning study?

2. What are the principal elements of the first question which should be answered by the study?

3. What are the principal elements of the second question which should be answered by the study?

4. A plan for a new highway should cover transportation needs for some time into the future. How far into the future?

5. Who should fix the exact location of a new route?

6. In addition to the DOT what other agencies do highway planning?

7. Besides highway planning, what other types of planning are these other agencies involved in?

22194

F. Personal Attributes

1. Punctuality

2. Physical health

3. Integrity

4. Leadership

5. Attitudes

G. Personal Efficiency in Identifying Responsibility, Planning and Organizing Work and Work Stations.

Supplemental Teaching Aids:

Excellent resource people for this unit are working secretaries, State Department of Public Instruction personnel, beauty school operators or department store buyers, and nurses.

The best general resource book is the Arizona State Department of Vocational Education's Suggested Curriculum Guide in Vocational Office Procedures. A good resource for role playing is Case Problems: for Vocational Office Block Project. This is available from the Department of Vocational Education also. Other useful resource books are: You as a Secretary, Royal Typewriter Company. How to be a Super Secretary, Remington Rand, and Sheaffer's Handbook for Secretaries, W. A. Sheaffer Pen Co., Fort Madison, Iowa ($1).

Some very good films are applicable to this unit. For example; "Office Etiquette" (15 min.), Britannica Press, Chicago, Ill., "Office Teamwork" (12 min.), Britannica Press, and "Off to a Beautiful Start", Scott Paper Co., Philadelphia, Pa.

Training Time 5-7 hours

8. Why should the DOT coordinate its highway planning with other planning groups?

ASSIGNMENT

1. Read pages 377-379 and 420-430 in Ref. A. Write 100-200 words explaining the difference between highway planning and preliminary engineering.

2. Review Chapter 717 in Ref. C.

3. Review Section 134 in Ref. D.

4. Read pages 2-6 to 2-19 in Ref. F.

5. Read Chapter 1 in Ref. I.

6. In Ref. N read: "Integrated planning," October 1960 issue; "Highway planning in a small community," April 1965 issue; and "A scenic approach to roadbuilding," October 1965 issue.

22195

Lesson 3
Highway Agencies and Systems in New York State

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill. 1960. (Referred to in this unit as "Ref. F")

OBJECTIVES

1. To acquaint the students with the various highway agencies and systems in New York State
2. To show why planning for State highways should be coordinated with planning for other highway systems

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Highway Agencies in New York State	Explain why it is important to know about agencies other than the Department of Transportation which also have responsibilities for highways.
A. Public agencies	Point out to the students that public agencies are established by law and are nonprofit organizations.
1. New York State Department of Transportation	State that this new agency has taken over the responsibilities for highways previously held by the former Department of Public Works. The DOT is also responsible for aviation, public transportation, and traffic regulation.

22196

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. United States Government Department of Transportation	Explain that the U.S. Bureau of Public Roads, formerly in the Department of Commerce, is now a unit of the Federal Highway Agency in the new U.S. Department of Transportation. The functions of the Bureau of Public Roads (BPR) are unchanged.
3. County	Point out to the students that each county has a road system, and usually has an organization responsible for the system. Display a map of a county road network.
4. Town	Describe a typical town road system and point out its routes on a map. Mention a typical organization responsible for town roads.
5. City, village, and other subdivisions	Show the students maps of city and village streets, and mention the kind of organizations that are responsible for them.
B. Quasi-public agencies	State that quasi-public agencies are established by law in the public interest. A good example of one which controls construction, maintenance, and operation of highways is the New York State Thruway Authority. This agency and other quasi-public agencies have characteristics of both a public agency and a private business.
II. Highway Systems in New York State	Inform the students that all highway systems change from time to time to meet current or anticipated needs for service.
A. Highways receiving Federal aid	Explain that New York State, like other states, relies heavily on financial aid from the U.S. Government. For Federal aid purposes, highway systems are classified as primary and secondary. A primary system of highways connects urban centers and has a high traffic count; a secondary system connects smaller, non-urban areas, and carries less traffic. The Government financing for primary highway systems differs

22197

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
d. Parkways	Explain that some parkways are expressways as far as traffic service is concerned, but do not permit commercial traffic. Mention that some parkways are also in the Federal Aid Primary (FAP) highway system.
B. Highways not receiving Federal aid	Remind the students that the Federal Government does not participate in financing and planning *all* roads in a state.
1. State system	Point out to the students that there are many miles of State highway not on either the FAP or the FAS system. These are special purpose roads such as access roads to State parks, stub connections, and alternates to FAP and FAS roads.
2. County system	Explain that not all county roads are part of the FAS system. For some the county bears full financial responsibility.
3. Town roads	On a map with town roads show that these are only minor feeders to the county or State systems and do not qualify for Federal aid.
4. City and village streets	Explain that the many thousand miles of city and village streets do not usually qualify as either trunk routes, collectors, or feeders. Those in cities that do qualify are usually arterials; those in villages are usually State highways.
C. Quasi-public highways	Remind the students that quasi-public agencies have characteristics of both a public agency and a private business. Explain that Federal law and policy do not permit Federal participation in construction, operation, or maintenance of a toll highway. State that parts of highway projects under a quasi-public agency may be Federally-aided upon meeting the con-

22199

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	dition that the public can use the highway without paying toll. Example: The Cross-Bronx Expressway, where westbound traffic is not required to use the George Washington Bridge but can exit to free roads.
III. Coordination Among Highway Agencies	Explain that all highway systems together make up an integrated transportation network for vehicles. Point out that no highway agency can plan without knowledge of the plans of other agencies because practically all highways in the State are very much interrelated. Impress on the students that all funds for highways are public money, including funds of quasi-public agencies. Coordinated planning can save the public many dollars.
IV. Summary	Present a summary covering the highway agencies in New York State. Do the same for the highway systems in the State. Sum up the importance of coordinated planning by all highway agencies. Remind the students that it is very easy to look at a small part of one highway and forget the big interrelated system of which it is a part.

QUESTIONS FOR REVIEW

1. What new concept is being implemented by the creation of new Federal and State highway agencies?

2. What other agencies in New York State besides the Department of Transportation are responsible for highways?

3. Are all these other highway agencies classified as *public* agencies?

4. Are all State highways part of the Federal aid system?

5. Are any city streets part of the Federal aid system?

New York State Department of Public Works, Bureau of Programming. Rating physical sufficiency of New York State highways. The Department, Albany, New York. 1961. (Referred to in this unit as "Ref. J")

New York State Department of Public Works, Bureau of Programming. Town and county road inventory. The Department, Albany, New York. 1962. (Referred to in this unit as "Ref. M")

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill. 1960. (Referred to in this unit as "Ref. F")

OBJECTIVES

1. To acquaint the students with the elements of road inventory and field scoring
2. To fit the inventory and scoring into the highway planning process

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Inventory of Roads	Explain that highway planning starts with a knowledge of what roads are on hand. Also explain that the Department of Transportation has developed changes in the type and amount of detail required for the inventory. Inform the students that Ref. K is the manual used for road surveys. Ref. J has been superseded but is useful for background information.

6. What is the functional difference between a Federal Aid Primary road and a Federal Aid Secondary?

7. Does the Federal Government contribute towards the cost of roads built by an agency like the East Hudson Parkway Authority?

ASSIGNMENT

1. Read pages 85-90 in Ref. A.

2. Read pages 5-8 in Ref. B.

3. Read pages 2-6 to 2-8 in Ref. F. Write 100 to 200 words on setting up a system of expressways which would receive Federal aid.

4. Read the sections about highway agencies in Ref. G.

5. Read Ref. H.

22201

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	centages listed above to give a maximum total of 100% for top conditions. A lesser score is given when each element is less than ideal.
C. Relation of volume to capacity	Tell the students that whenever a traffic jam occurs on a road the cause is insufficient capacity, not poor structural condition. Point out that a road may be in good condition structurally and be well maintained, but its width may be inadequate for the traffic volume it carries. As a part of field scoring we use an additional rating factor to reflect the volume-to-capacity relationship.
1. Ref. U, good source	Tell the students that many types of studies have been used to measure the capacity of roads and streets. Show Ref. U and state that this is a national reference book and is an important tool for the DOT.
2. Meaning of volume-to-capacity scores	Explain that for the volume-to-capacity ratio, a score of 118 or less indicates a satisfactory condition. A higher score denotes an unsatisfactory condition.
III. Sufficiency Ratings	State that field scores are useful only if they are translated into meaningful numbers. The rating for structural and maintenance conditions combined with the score for volume-to-capacity gives a *sufficiency rating*, which is an overall rating for the road.
A. Averaging field scores	Explain that the above scores are averaged to obtain a sufficiency rating. For example, suppose a road has a structural score of 40 and a volume-to-capacity score of 100. The sufficiency rating of this road is 70. A road with scores of 100 and 40 (rather than 40 and 100) also has a sufficiency score of 70. However the first road is deficient structurally, while the second

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	road is new and has low traffic volume.
	Explain that averaging is useful to compare general road conditions throughout a county, a district, or the State from one year to another. However, no specific improvement programs are developed from averages.
B. Index number	Tell the students that the DOT uses a system of machine methods which takes into account the individual scores and determines the nature of the improvement needed, by index number.
C. Engineering judgment	State that not all engineering decisions can be based solely on the answers from a computer.
	Point out to the students that the field scoring team makes a recommendation for road improvement, based on judgment, from the observed factors. Conclusions reached by judgment are checked against the machine computation for consistency.
IV. Summary	Remind the students that a road inventory is merely a collection of facts used to arrive at an evaluation. Changes are then recommended on the basis of the evaluation.
	Summarize the steps required for a road inventory and the field scoring elements involved.
	State that a complex planning study requires a very detailed inventory. A study for a small region, however, usually requires only a minor amount of detail.
	Briefly mention the scope of the next lesson.

QUESTIONS FOR REVIEW

1. Why is a road inventory necessary?

UNIT II (14.0406-02)

FUNDAMENTALS OF TYPING

Performance Objectives:

Upon completion of this unit the student will be able to type at a rate of 30 wpm/ecol.

Unit Outline:

A. Machine Fundamentals

1. Parts

2. Maintenance procedures

3. Manual and electric typewriters

4. Operation

B. Quality and Performance Standards

1. Speed and accuracy

2. Neatness

3. Language arts

C. Skill Development

1. Keyboard mastery

2. Manipulation of machine parts

3. Speed, accuracy and erasing

D. Typing Applications

Supplemental Teaching Aids:

No suggestions will be made for this unit since free or inexpensive resources are not applicable

Training Time 70-85 hours

2191

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Elements of the inventory	Tell the students that there are many elements that make up a road inventory. A few are discussed in this lesson to illustrate principles only.
1. Length of roads	State that it is not necessary to send a transit party out to measure the mileages of State highways. Mileages can be measured accurately enough for highway planning by using special automobile odometers which read to hundredths of a mile. The automobile tire pressure must be checked daily and adjusted, if necessary, to maintain accuracy of readings. Point out that a fifth wheel geared to a measuring device may be attached to a car bumper and used as an alternate method for mileage measurements.
2. Width of roads	Remind the students that a planning survey inventory does not require great precision. Pavement and shoulder widths measured to the nearest foot give enough accuracy for this survey.
3. Type of paving	Mention that the type of pavement is an important element of the inventory. This information is used to determine the nature and cost of improvement, if the existing road is to be kept and developed.
4. Development of surrounding areas	Tell the students that the nature and extent of development of the area adjacent to each road is important. This information is used when alternate corridors on new locations are evaluated. Also the area development pattern must be known to estimate the cost of the right-of-way.
B. Uses of inventory data	Emphasize that the DOT requires varying degrees of precision in road inventories, determined by the purpose served by each.

22203

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. For highway planning	Inform the students that the basic data for planning studies are available from the periodic road inventories that are conducted. Point out that a planner for State highway systems cannot be fully effective without a thorough knowledge of other road systems. For example, he needs data on local road and street widths and mileages, for vehicle-mile forecasts or *needs* studies.
2. As basis for allocating aid to towns and counties	Explain that the State gives financial aid to local governments based on mileages of existing roads. These mileages are determined from the inventories.
II. Field Scoring	Tell the students that field scoring is a way of evaluating the condition of a road and its adequacy for the volume of traffic it carries. Considerable judgment and experience are required to make this evaluation. State that there are several factors in the field scoring system. The Resident Engineer for the area is part of the scoring team that rates a road.
A. Surface and structural condition	Tell the students that the surface condition of a road is given a maximum score of 30% and the degree of rupture is given a maximum of 40%. Explain that inspection of surface condition and extent of rupture by an experienced scorer can reveal the underlying problems of sub-base, drainage, and other valuable engineering information. We can then use this data in various phases of highway development.
B. Maintenance condition	State that the condition of the road based on degree of maintenance is given a weight of 30%. This element of the score is used with the per-

22204

2. What are the principal elements in an inventory?

3. Why isn't a topography survey included in the inventory?

4. Why is a specialist required to conduct field scoring?

5. What improvement should be recommended if:

   a. A road is deficient structurally?

   b. A road is deficient in volume-to-capacity ratio?

   c. A road is deficient in both a and b?

6. How would an inventory be made for highway planning in a large urban area?

ASSIGNMENT

1. Read pages 2-9 in Ref. F.

2. Read Ref. J and Ref. K. Write in 100 to 200 words your ideas on the need for updating a road inventory every year.

3. Read Ref. L.

4. Read Ref. M.

Lesson 5
Mapping As A Planning Tool

REFERENCES CITED IN THIS LESSON

New York State Department of Public Works, Bureau of Programming. Prospectus for a highway-planning mapping program. The Department, Albany, New York. 1965. (Referred to in this unit as "Ref. O")

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill Book Company. 1960. (Referred to in this unit as "Ref. F")

OBJECTIVES

1. To acquaint the students with the kinds of maps in common use for highway planning
2. To show the students the uses of different kinds of maps in highway planning, highway engineering, and related fields

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Kinds of Maps	Explain that there are a great many kinds of maps, including those for special purposes. This lesson will discuss only the few types concerned with highway planning. Point out that maps are used in a great many activities, ranging from navigation to census taking. Mention that maps are important tools for planning. Those used in planning are custom-made for each need.
A. *Planimetric* maps	Tell the students that *planimetric* or *flat* maps are adequate for many purposes. Cite several uses for this type of map. Show a preliminary plan drawn to a scale of 1" = 200' and describe its use without revealing the scale. Ask the students to try to determine the scale by guesswork.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Highway planning series (HPS) county maps	Mention that in 1940 the Department of Public Works prepared a series of highway planning maps using several scales: 1" = 1 mile, 2" = 1 mile, and 1" = 2000'. County maps are part of this series. Point out that this variety of scales was based on available sources for the map features and on the intensity of development in the areas mapped. Inform the students that years of experience have shown that the most useful map scale for general highway planning is 1" = 1 mile.
2. HPS city maps	Explain that the city map series has been tailored to fit standard-size map sheets. Therefore, not all maps in the series use the same scale. Mention that city maps are made with many different scales and with varying detail to suit a particular purpose. Illustrate with assessment maps, plot plans, sewer and water maps, and maps of other utilities.
3. Travel guides and atlases	Remind the students that maps are tools. Briefly discuss the tourist guide series and the atlases prepared for the major oil companies by General Drafting Company, Hagstrom, Baker, etc.
4. *Sanborn* maps	Show a typical *Sanborn* map sheet and briefly explain the details included on it. Remind the students that a given type of map can be used for many purposes. Ask the class to cite a few uses of Sanborn maps.
5. Photomaps	Explain that mapping is a science, and that research is constantly being conducted to produce better maps.

22209

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Inform the students that the Department of Transportation made an exhaustive study on the possibility of using aerial photos as base maps, with all important features labeled.
	Mention that after several years of testing, the idea was dropped because of unsatisfactory results.
B. *Photogrammetric* maps	Tell the students that for certain purposes it is important to have the third dimension added to a flat map.
	Mention that the science of aerial photography has developed to such a high degree that three-dimensional maps can be produced quickly and cheaply.
	State that photogrammetric methods have produced much contour information. This cuts out the need for a ground survey of every inch of an area.
1. Ground controls needed	Explain that some ground survey work is necessary to provide base elevations and to check the accuracy of the contours.
2. Map scales used	Mention that the most convenient scale for preliminary engineering is 1" = 200'; for detail design 1" = 50'. Maps for complex designs such as interchanges are usually at 1" = 20'.
C. United States Geological Survey (USGS) maps	
1. Functions of USGS	Describe briefly the role of the USGS, explaining the functions of its triangulation stations and other control stations.
	State that the USGS is also eliminating much of the old-time theodolite and plane table methods in favor of the newer aerial photography techniques.

22210

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Updating of maps	Explain the new program of updating USGS sheets at a scale of 1" = 2000' for 7½-minute quadrangles. Point out that ground controls are especially important for USGS maps because of the large area they cover. Ask students if they know what scale the USGS formerly used for most of its mapping. The correct answer is 1:62,500.
D. Aerial photographs	Inform the students that aerial photos are not maps in the strictest sense, but are enlargements of vertical photos of surface areas.
1. The usual scale	Tell the students that the usual scale for a route study is 1" = 400'. Show an aerial photo and draw a line on it with a grease pencil to illustrate that it can be made into a route study map.
2. Another scale used	Indicate that where right-of-way is the critical factor, the 1" = 50' scale is used for a quick office study of alternate routes. Mention that the photos with a 50' scale are often used to lay out ROW maps.
II. Uses of maps	Remind the class that maps are tools and each type serves a specific purpose.
A. Planimetric maps	Explain that planimetric or flat maps fill many needs. Point out that time and money will be wasted if contours are obtained when not needed.
1. HPS county maps	Show a section of an HPS county map with several colored lines drawn on it as route relocation alternates. Mention that a map of this kind is not used for design but for evaluating general location factors.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. HPS city maps	Repeat the procedure with an HPS city map, showing several alternates. Point out that planning for a complex area requires advanced techniques and many detailed maps.
3. Travel guides and atlases	Tell the students that for a broad look at a regional corridor study, an oil company map would be sufficient. Ask them to explain why this type of map is sufficient.
4. Sanborn maps	Explain that a Sanborn map gives the accurate detail needed in cities for insurance rating, assessment, zoning, building codes, etc.
5. Photomaps	Point out that the photomap is better than other planimetric maps. If a good reproducible photomap could be made inexpensively, it would be used more than other planimetric maps.
B. Photogrammetric maps	
1. Main uses	State that a photogrammetric map is used primarily for locating and designing roads. Because its cost is very high, this map is not used for highway planning. Show a highway location on a map drawn to a scale of 1" = 200'. Explain that adding contours to the map permits the plotting of lines to show feasible construction.
2. Other uses	Tell the students that this kind of map is quite satisfactory for comparing alternate lines, establishing grades, etc. Mention that they can also be used for review by the main office of the DOT, the Bureau of Public Roads, and for a public hearing.
C. USGS maps	Explain that the scale of the USGS maps makes them less useful than photogrammetric maps for *small* areas. For regional studies or for long route sections,

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	however, their 1" = 2000' scale, their contours, and other topography details make them more useful.
D. Aerial photos	Inform the students that aerial photos are not only used for general review but also for plotting lines and other features. Therefore, these photos must be taken vertically, not obliquely. Indicate that 1" = 400' is usually a good scale for route studies, but a 1" = 50' scale is more useful for design, especially in ROW work. Remind the students that interpretation of aerial photos is a very complex technique, used for geological, agricultural, and other work. And point out that the class is considering only one or two uses of aerial photos.
III. Summary	Begin summarizing by stating that maps are highly specialized tools and that the discussion has been limited to only a few of the many types. Summarize the pertinent information about the various types of maps. Explain that highway planning involves the location of corridors and not the preliminary design of a highway.

QUESTIONS FOR REVIEW

1. What is another name for a *flat* map?
2. What is the best scale for a map?
3. Should all maps be prepared to the same scale to avoid confusion in measuring?
4. Would an oil company map be of any use in a highway planning study?
5. What is the difference between a *planimetric* map and a *photogrammetric* map?
6. What are the differences among a photomap, photogrammetric map, and an aerial photo?

22213

7. What is the main use for a photogrammetric map?

8. What is the main use for a Sanborn map?

9. What is the objection, if any, to using oblique aerial photos for highway planning?

10. What is the current, updated scale for USGS maps?

ASSIGNMENT

1. Read pages 2-11 and 2-12 in Ref. F.

2. Read Ref. G. Write 100-200 words comparing a mapping program prepared by a commercial map company to a program prepared by DOT staff.

22214

UNIT III (14.0406-03)

OFFICE EQUIPMENT

Performance Objectives:

Upon completion of this unit the student will be able to score 90% or above on an instructor established scale that considers both accuracy and time, in operation of adding machines and calculators.

Unit Outline:

A. Ten-key Adding Machines and Printing Calculators

1. Adding by touch

2. Subtraction

3. Multiplication

4. Decimals and factions, conversions

5. Division on printing calculators

Supplementary Teaching Aids:

No resource book suggestions are provided due to the nature of this unit. As a general overview of business machines the following film might be considered; "Modern Business Machines", Teaching Aids Exchange, 307 South B Street, San Mateo, Calif. 94401.

Training Time 10-15 hours

Lesson 6
Traffic Studies

REFERENCES CITED IN THIS LESSON

Matson, T.M., Smith, W.S., & Hurd, F.W. Traffic engineering. New York. McGraw-Hill. 1955. (Referred to in this unit as "Ref. I")

New York State Department of Public Works, Bureau of Highway Planning. External survey manual. The Bureau, Albany, New York. 1966. TM 00-112-01R1. (Referred to in this unit as "Ref. R")

New York State Department of Public Works, Bureau of Highway Planning. Urban area reports. The Bureau, Albany, New York. (These consist of 60 reports, each on a separate urban area, published between 1946 and 1956.) (Referred to in this unit as "Ref. Q")

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill. 1960. (Referred to in this unit as "Ref. F")

OBJECTIVES

1. To acquaint the students with the various types of traffic surveys and studies forming the basis for highway design
2. To show how each serves a specific purpose in highway planning for smaller areas
3. To introduce the students to the more detailed types of traffic studies required for complex areas

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Volume Counts of Traffic	Explain that counts of traffic volume are records of the passage of vehicles across a given point in a given time.
A. Machine method	Tell the students that previously counting was accomplished by manual means. Modern traffic volume requires use of machines to count vehicles. State that traffic counters have been improved to a very high degree of reliability.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Indicate that there are several types of *detectors* and that constant research is being conducted to develop new and improved types.
1. Fixed detectors	Inform the students that the principal types of detectors are: a. treadles which count axles b. radar and ultrasonic devices which emit beams that reflect from vehicles c. infrared and electric eye detectors that have beams which are interrupted by vehicles d. electromagnetic and loop detectors placed under the pavement. This type emits electric fields which are interrupted by vehicles
2. Portable detectors	Explain that for short counts it does not pay to install a fixed detector, and a portable one is used. For this purpose we use rubber tubes laid across the road, connected to the recorder.
3. Printed-tape recorders	State that in a printed-tape recorder the impulses from the detector actuate a mechanism which counts traffic and prints the count on a tape. Recorders can be battery operated or be connected to regular electric-line current.
4. Punched-tape recorders	Explain that punched-tape recorders print out vehicle volume data on a tape. This information is later translated to IBM cards.
5. Computer control	Mention that it is possible to have traffic counters connected to a *computer center* where the data can be automatically processed. This type of installation is very expensive and is used only for special applications.
B. Manual method	Point out that for turning counts at intersections, or other short term needs, use of machines is not practical. Purposes such as these can be satisfied by taking counts manually.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Inform the students that there is no benefit in getting more information than we need for the study purpose. For example, data for an intersection design may be adequately obtained by a manual count of 8 to 12 hours.
II. Origin and Destination (O & D) Surveys	Remind the students that the class is considering highway planning for a small area and is not concerned with an urban transportation study.
A. Roadside interview	
1. *Spot survey*	Point out that a one-station survey *(spot survey)* is the simplest type for data collecting.
2. *Screen line*	State that *screen lines* consisting of stations for taking data may be thrown across any series of routes. This type of survey is necessary for comparing *alternate* corridors.
	Show a map with two alternate parallel corridors and a screen line cutting across the corridors. Explain that at least two stations should be operated as part of the screen line.
3. *Cordon* around an area	Mention that for study of a village bypass it would be necessary to encircle the area with a *cordon* of interviewers and checkers to get a comprehensive O & D pattern.
	Tell the students that complex areas require more sophisticated studies, both for O & D surveys and for traffic counts.
B. Other O & D surveys	Name a few other types of O & D surveys. These include: home interview, destination interview, questionnaire postal card, license plate survey, telephone interview, and headlight survey.
III. Classification Counts	Tell the students that it is important to know the composition of traffic. This information, which is obtained by

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	a *classification count*, is used for various aspects of highway planning.
	Point out, for example, that heavily traveled truck routes require heavier pavement, bigger ramp radii, etc.
A. Comprehensive data collection	Explain that important routes under study require classification counts all year (on a 24-hour basis) to obtain daily and seasonal composition patterns.
	Inform the students that the classification system for vehicles is quite detailed. For example, trucks can be classified into 15 or more groups.
B. Short-term count	State that a short-term classification count is often sufficient for planning purposes. Point out, for instance, that if a count is needed for a day's traffic peak, a count from 4-5 P.M. at the Holland Tunnel would probably give it.
IV. *Turning-Count*	Show a sketch of an intersection and ask the students which legs should be counted for a *turning-count*. The proper answer is that all four legs must be counted, including the legs for through traffic, and those for left and right turns.
	Mention to the students that a turning-count is a good example of a manual count. Explain that turning-count information is used to design left and right turning lanes.
V. Uses of Traffic Surveys	Review the previous parts of the lesson covering traffic counts, O & D surveys, classification counts, and turning-counts.
	Ask the students if they can give one major use for each of these types of traffic study. Acceptable answers are:

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	a. Traffic count--the data from a count is translated to AADT and DH. b. O & D survey--survey information is used to determine bypassable traffic areas. c. Classification count--the resulting information is used in designing the geometrics of a road. d. Turning-count--the information is used in designing intersections.
VI. Summary	Point out that the general purpose of traffic studies is to give the highway planner the data he needs to make intelligent recommendations to the designer. State that the decision whether to build a new highway or to improve an existing one must be based on sound analytical data. The high cost of highways does not allow any guesswork in decision-making. Tell the students that wide reading is required to promote their understanding of highway planning and highway engineering. Briefly mention the scope of the next lesson.

QUESTIONS FOR REVIEW

1. What are the principal elements of a traffic study for highway planning?

2. What is the basic difference between a treadle detector and a tube detector? Between a treadle detector and a loop detector?

3. Where would you use computer control for traffic count-information?

4. Why are O & D surveys made?

5. When would a home-interview survey be used? A screen-line survey? A spot O & D survey?

22219

6. Of what value is a classification count in a village bypass study in dairy country?

7. What kind of traffic study should be made for intersection design?

ASSIGNMENT

1. Read pages 2-13 to 2-18 in Ref. F.

2. Read Chapters 5 and 6 in Ref. I.

3. Read pages 53-58 in Ref. P.

4. Read any one of the reports in Ref. Q.

5. Read Ref. R. Write 100 to 200 words on what you would do to solve the problems of a congested state highway in a village where diagonal parking is permitted in front of stores.

Lesson 7
Traffic Analysis

REFERENCES CITED IN THIS LESSON

Matson, T.M., Smith, W.S., & Hurd, F.W. Traffic engineering. New York. McGraw-Hill. 1955. (Referred to in this unit as "Ref. I")

New York State, Department of Public Works, Bureau of Highway Planning. Urban area report. The Bureau, Albany, New York. (Referred to in this unit as "Ref. Q")

Traffic Quarterly. The Eno Foundation for Traffic Control, Saugatuck, Conn. (Referred to in this unit as "Ref. N")

Winch, D.M. Economics of highway planning. Toronto, Canada. University of Toronto Press. 1963. (Referred to in this unit as "Ref. T")

OBJECTIVES

1. To show the major steps in making a simple traffic analysis for a small-area study
2. To show how an analysis is used in highway planning for such an area

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Analysis of Traffic Volume	Explain that raw data on traffic volume are most useful when translated into two standard measures: average annual daily traffic (AADT) and design hour (DH).
A. Average annual daily traffic (AADT)	Mention that traffic volume varies with the hour of day and the season of the year. State that the most useful indicator of traffic load on a highway is the AADT, which is the average traffic volume for each day of the year.
1. Continuous count	Display a graph which shows traffic volume by hour of the day and another which shows volume by day of the year.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Explain that records from a continuous counter provide counts 24 hours a day and cover all of the 8760 hours of the year. Dividing the year's total by 365 gives the AADT.
2. Short count	Tell the students that portable counters are used for a short count. They are shifted from place to place in accordance with a schedule, or to meet a specific need. Ask the students for their ideas of the definition of a short count. State that many studies have been made on the desirable length of a short count. Explain that some are taken for only 24 hours, but others are taken for 7 days to get the week-end traffic volume. Point out that short counts must be translated to AADT by using conversion factors. Show an annual curve with the AADT line through May and October. State that from continuous counts, factors are derived to convert short counts into annual data.
B. Design hour (DH)	Tell the students that a design hour is the volume of traffic per hour for which the highway is designed.
1. With a continuous count	Explain that where continuous records of traffic are available, the 8760 hours of the year are arrayed in decending order of traffic volume. The 30th highest hour in this array is most commonly used for design. Ask the students to explain why. Inform the class that it would be uneconomical to design roadways for the small percent of the total year's traffic above the 30th highest hour.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Point out that in designing special roads, such as those with highly seasonal traffic, the DH may be other than the 30th hour. For such roads it might be desirable to use the 50th or the 80th hour.
	State that the choice of the DH is based on economics plus engineering judgment.
2. With a short count	Mention that for short counts a complete array of the hours of the year cannot be made. In such cases a computation is made to determine the DH.
	Explain that the Albany office of the New York State DOT has traffic data covering many years and has made many studies to derive conversion factors. The AADT and the DH are computed in Albany from short count data furnished by the districts. The computed figures are then given to the districts as required.
C. Composition of traffic	State that it is important to know the composition of traffic.
1. Equivalent traffic count	Show on the chalkboard that 100 vehicles consisting of 5 trucks and 95 passenger cars is equivalent to 105 passenger cars. (This assumes an average truck factor of 2.)
	Also show that 100 vehicles consisting of 5 tractor-trailers and 95 passenger cars is equivalent to 115 passenger cars. (This assumes a tractor-trailer factor of 4.)
2. Effect on road design	Ask the students to enumerate road features that could be affected by a large volume of heavy trucks. These include lane width; pavement thickness; subbase type and thickness; shoulder type, width, and thickness; grades, including climbing lane, ramp widths, and radii.

22223

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
II. Analysis of Travel Characteristics	Mention that up to this point the lesson is concerned only with actual traffic on existing roads. Point out that volume studies do not help to determine whether traffic can be bypassed.
A. Origin and destination (O & D) surveys	Tell the students that O & D spot, screen line, and cordon surveys were designed to determine what traffic can be bypassed.
1. Through traffic	Explain that through-traffic can be classified into two types: *long-distance* and *area*. Discuss with the students the difference between *area* through-traffic and *long-distance* through-traffic. Explain that traffic in a business district which originates within a certain number of miles from the center point of the district is *area* through-traffic. Traffic originating further away than that is *long-distance* through-traffic. Ask the students what that number of miles is. (The correct answer is 25 miles.) State that for some studies the difference between the two types of through-traffic is significant, and for other studies it is not. To find out if any students have a grasp of regional planning, ask the class why this situation might exist.
2. Local traffic	Remind the students that this course is concerned with elements of highway planning. Mention that the principal traffic problem in villages and small cities is the main street congestion caused by shoppers, etc. Explain that the percentage of total traffic in large cities which can be bypassed varies with population. In villages and small cities a significant percentage can always be bypassed.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Note that it is pointless to split a small area into many O & D survey zones when you want to decide only whether to bypass or not to bypass the area.
B. Assignment of traffic to a bypass	State that once the O & D survey data are analyzed, it is easy to assign traffic either to an existing route or to a proposed bypass. This assignment will be based on the origin and destination of travelers, and on the time-distance ratio as shown in a diversion curve.
1. Diversion curve	Tell the class that most people will drive their cars on a long, round-about route to avoid the congested traffic on a shorter route. Show a *diversion curve* and point out the breakeven point.
2. Variations from the curve	Impress on the students that some people have personal preferences and habits that do not follow a scientific curve. Therefore, it is unwise to base the assigning of traffic completely on the curve. Some allowance should be made for these preferences and habits. Point out that 20 to 25% of divertable traffic will not divert. Therefore, no bypass should be justified by a curve only.
III. Applications of Traffic Analysis	Remind the students that for all engineering work the objective should be clearly stated. Mention that all the analyses above are aimed at helping to arrive at a high-way-planning decision.
A. Improving existing routes	Sketch a village grid system on the chalkboard and show Main Street with volume notations of 800 DH and 8,000 AADT. Explain that these volumes impose too heavy a traffic load for a two-lane highway.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	State that an O & D analysis showed that only 25% of the traffic was bypassable and 75% would theoretically stay on Main Street. Remind the students that some of the 25% will also choose not to use the bypass.
	Conclude for the students that this analysis calls for improving the existing route. Ask for suggestions on ways to make improvements.
1. Ways of improving	Show that there are many possibilities for improving the road, such as: widening toward one side, widening toward both sides, establishing one-way couples, and widening a parallel street and rerouting through-traffic.
B. Planning a bypass	Reverse the figures of the example and tell the students that 75% of the traffic is bypassable. Caution the class again about using the full percentage in planning diversion of traffic.
	Sketch a bypass around the village following the general direction of the desire lines from the O & D survey.
	Point out that at this point in the planning the problem enters the engineering stage.
	Draw the conclusion for the class that Main Street won't need widening when 50 to 60% of the traffic uses a bypass.
IV. Summary	Explain that this lesson has considered only existing traffic and that forecasting will be studied later.
	Point out that forecasts of traffic volume are normally used in highway planning studies and, perhaps, should have been presented in this course before now. Instead, traffic forecasting is the next lesson. This order is followed to maintain continuity of travel characteristics.

Lesson 9
Economic Analysis

Hay, W.W. Introduction to transportation engineering. New York. John Wiley. 1961. (Referred to in this unit as "Ref. A")

New York State Executive Department, Office for Regional Development. Change, challenge, response. The Office, Albany, New York. 1964. (Referred to in this unit as "Ref. X")

Winch, D.M. Economics of highway planning. Toronto, Canada. University of Toronto Press. 1963. (Referred to in this unit as "Ref. T")

Woods, K.B. Highway engineering. New York. McGraw-Hill. 1960. (Referred to in this unit as "Ref. F")

OBJECTIVES

1. To show the major steps in making an economic analysis for a highway planning study of a small rural area
2. To show how an economic analysis helps the highway planner in decision-making

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Economic Analysis in Highway Planning	Point out that each phase of highway planning has a specific purpose. Economic analysis is also a phase of highway planning, and an important one.
A. Decision-making	Emphasize that professionals do not use guesswork in economic analysis but base their decisions on all facts available. They use judgment, which is the application of professional experience to a specific set of facts. Explain that the highway planner must prove the value of his recommendations to many individuals and many agencies.
B. Presentation	Tell the students that a planning study must be thorough and of high quality. It must be written so its value will be evident to people unfamiliar with highway planning.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

Tell the students that highway planning is invaluable, even for areas with very simple traffic problems.

QUESTIONS FOR REVIEW

1. If traffic studies are carefully made, can they be used by the highway planner as raw data?

2. What are the standard traffic measures? (Suggested answer: AADT and DH.)

3. Is there any objection to taking all short counts in either May or October? If so, what is it? (Suggested answer: Too much equipment is required.)

4. What is the objection, if any, to using the 30th hour as the DH on a road leading to a racetrack?

5. Why is a factor as big as 4 applied to tractor-trailers in a traffic count, when converting to equivalent passenger vehicles? (Suggested answer: A tractor trailer interferes with the sight-distance of vehicles behind it; it takes up a considerable length of roadway; it is difficult to pass; it climbs hills slowly; and it requires a large side-clearance.)

6. What is the basis for assigning traffic to either an existing road or to a proposed bypass?

7. Will a bypass hurt village business? If so, how?

8. Suppose an O & D survey of Main Street indicates a 50% theoretical diversion to a bypass. What improvement should be made if Main Street is 30 feet wide? 40 feet wide? 50 feet wide?

   Suggested answer: For 30 to 40% diversion, a bypass would be practical for the 30- or 40-foot street. Approximately one-third relief would be obtained. Although small, this improvement could allow the street to operate efficiently. For a 50-foot street it is possible to operate 4 lanes, with one side lane for parking. But this would probably leave the village dissatisfied. Therefore, a bypass would be recommended for all cases, if present volumes are critical.)

ASSIGNMENT

1. Read Chapter 37-4 in Ref. I. Write 100-200 words giving arguments you would present in explaining the need for a bypass to a Chamber of Commerce.

UNIT IV (14.0406-04)

COMMUNICATIONS

Performance Objectives:

Upon completion of this unit the student will be able to demonstrate to the satisfaction of the instructor a level of coherence and clarity in oral communications that is adequate for the business office. In an objective test the student will be able to score at least 80% on items covering mail handling and telegraph techniques and procedures.

Unit Outline:

A. Elements of Good Speech

1. Voice control

2. Vocabulary, pronunciation

3. Grammar and writing

B. Speech Problems

1. Individual analysis

2. Corrective program

C. Business Office Uses of Telegrams

1. Comparison with other uses and forms of communications

D. Methods of Sending Messages and Various Systems

E. Types of Services and Rates

F. Processing Activities

1. Incoming

2. Outgoing

G. Importance of Mail

H. Procedures for Handling Mail

I. Classification of Mail and Rates

J. Postage Equipment and Supplies

1. Postage meters and scales

2. Automatic addressing systems

2193

2. Read "An approach to O & D data analysis" in the April 1955 issue of Ref. N.

3. Read Ref. Q.

4. Read pages 30-34 and 93-95 in Ref. T.

Lesson 8
Traffic Forecasting

New York State Department of Public Works, Bureau of Highway Planning. Urban area reports. The Bureau, Albany, New York. (These consist of 60 reports, each on a separate urban area, published between 1946 and 1956.) (Referred to in this unit as "Ref. Q")

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill, 1960. (Referred to in this unit as "Ref. F")

OBJECTIVES

1. To acquaint students with the procedures for making traffic forecasts for road networks in small areas
2. To show how traffic forecasts, as developed through this course, are used in highway planning

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Principles of Traffic Forecasting	Tell the students that *traffic forecasting* requires engineering judgment applied to certain basic principles, which have evolved over the years from nationwide research. Forecast data is used in almost all phases of highway planning and engineering.
A. Selection of forecast period	Point out that each forecast is designed to meet a specific road need; it covers specified conditions for a specified period of time.
1. 10-year forecast	Cite as an example the use of field scoring and traffic studies which showed that a certain road needed only resurfacing. This resurfacing is estimated as having a 10-year life. Therefore, we limit our forecast to a 10-year period.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Explain to the class that in highway planning it is best to plan for a specified time period. Explain that all work must have a specific objective and our objective should be to meet the traffic needs of a given period in the future.
2. 20-year forecast	Point out that inventory and traffic studies could, in certain cases, indicate the need for either a new highway location or a major reconstruction of an existing road. State that in such cases it would be uneconomical to plan for only 10 years of traffic growth because the economic life of new pavement is estimated to be 20 years.
3. 30-year forecast	Tell the students that *structures* which form part of a highway system are designed for a 30-year life. Therefore we use a 30-year forecast for these structures.
4. Forecast for a longer period	Mention that a forecast for more than 30 years may appear to be unfeasible. But sometimes an estimate must be made for 40 or 50 years. Ask the class why forecasts for such a long period may be necessary. After discussion explain that they may be required for toll-road revenue studies.
B. Obtaining traffic figures for the base year	Explain that traffic counts are not made every year and often there will be no current count available when a forecast is being made. Point out that lack of a count is not serious because we base a traffic forecast only on estimates, using the best known techniques. When traffic information for the current year is not available, we derive it from earlier figures.

22230

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Declining trend	Show on the chalkboard the following three traffic-count figures for the years indicated:
	1957: $\frac{484}{5250} = \frac{\text{Design hour}}{\text{Avg. annual daily traffic}}$
	1959: $\frac{312}{4925}$
	1961: $\frac{115}{1911}$
a. Estimating the traffic	Ask students which figures they would use in projecting the future status of the road. Have them explain any choice they give.
	Conduct a discussion and then give the conclusion to the students that a decision could not be made solely on the basis of these three figures. Although the figures indicate a declining trend, these figures alone are not sufficient to arrive at a conclusion.
b. Analyzing the decline	Point out that the downward trend could be the result of traffic diverting temporarily because of construction or because a new road has been opened. Suppose we assume that a new road had opened in 1959. Traffic might still be using it for trips by an indirect route in 1961, simply because many people like to ride on a new road even if the trip is longer.
c. Overall study needed	State that the only sure way that we can determine whether there was a declining trend is to examine the road network of the whole area. Based on an overall study of all factors, we can arrive at a conclusion for the traffic trend.
	Emphasize that highway planners must be sure that their base year figures are accurate before proceeding with further planning.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Ask the students why accuracy at this point is important, to see if the class realizes that the forecast is projected from the base. This point must be well emphasized.
2. Static trend	Tell the students that extra care must be used in the analysis, if traffic seems to have stabilized on the road under study.
a. Analyzing the trend	Assume a prediction has been made that traffic on a certain road will not change for 20 years. Such a prediction is very unlikely to be correct because traffic rarely remains the same for any length of time. It must be analyzed periodically because unforeseeable conditions may arise. Explain that planning and design will be based on traffic forecasts and that we must use extreme care in selecting the base year.
3. Upward trend	Reverse the figures shown for the road with the declining trend. Ask the students whether they are satisfied that the figures truly show an upward trend.
a. Analyzing the trend	Explain that we must also use care in analyzing upward trends and arriving at conclusions, because factors not evident could be responsible for changes. Ask the class for possible conditions that may be causing the upward movement of traffic. One likely cause is that construction on other roads in the area is diverting traffic to the road being studied.
C. Expansion factors influencing forecasts	State that in making a traffic forecast all known factors that could influence the traffic must be considered. In this process we must apply the best engineering judgment to the latest and best traffic information.

22232

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Normal traffic	Point out that the economy is growing: there are more people, more and better highways, more automobiles, and incomes are going up. And there is more automobile use.
a. Auto registration going up	Draw a population growth curve and a vehicle registration curve on the chalkboard. Show that automobile registration is growing faster than the population.
2. *Generated traffic*	State that *generated traffic* results from unpredictable things such as curiosity and desire for movement, which motivate people to travel by car. There is no scientific basis for estimating this type of traffic.
a. Different from normal	Point out that generated traffic does not grow like normal traffic. Draw a normal growth curve and superimpose a *generation curve*, using an average 25% increase over 3 years. Show that the generation curve levels off after 3 years.
3. *Development traffic*	*Development traffic* is the increase in traffic on a new highway resulting from economic development along the highway. The economic development takes place in the *general traffic corridor*, an area on each side of the highway which follows it along its length or part of its length.
a. Economic development	This economic development includes the building of houses and the growth of business and industry. The houses are built to supply the normal growth of population. They are built in the general traffic corridor because of the travel convenience. The population growth in the corridor also stimulates the business growth to serve this population. The labor supply in the traffic corridor encourages the growth of industry.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Inform the class that this rapid development is not a flash boom but is an acceleration of the normal growth in the area.
	Draw a 30-year graph of development traffic. Show on it 20% growth in the first 10 years, 50% in the second 10 years, and 30% growth in the third 10-year period. These are, of course, only figures assumed for illustration, and can vary greatly from one place to another and from one time to another.
D. Computation for forecasting	Tell the students that once the three basic expansion elements have been determined we can reduce the rest of traffic forecasting to simple mathematics.
	Show a typical problem on the chalkboard using the three factors, and work out a 30-year traffic forecast in 10-year periods.
II. Uses of Traffic Forecasts	Remind the students that the objective of forecasting is to answer the questions, "How much traffic will there be, and when will it occur?"
	Point out that each area has its own characteristics and rate of growth. Therefore a traffic forecast should be tailored to suit the area. The highway planner should not use averages if specific information is available.
A. To determine the geometrics of roads	Tell the students that the designer uses the forecast figures to determine the geometrics of a road. Inaccuracies at this point could result in waste of millions of dollars.
III. Summary	Repeat that there is no magic in highway planning--only engineering judgment based on facts.
	Remind the students that the procedures taught in this lesson represent the application of scientific principles

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

to factual data collected and analyzed for a specific purpose--the forecast.

State that traffic forecasting has three main elements: the forecast period, traffic figures for the base year, and expansion factors.

Briefly mention the scope of the next lesson.

QUESTIONS FOR REVIEW

1. What are the elements of a traffic forecast?
2. What are the usual periods covered by forecasts?
3. What type of improvement is usually associated with each type of forecast period?
4. What is the best base year to use for a forecast?
5. What precautions should be taken when selecting a base year from a series of counts compiled over a period of time?
6. What are the principal elements in the growth of traffic?

ASSIGNMENT

1. Read page 424 and pages 426-428 in Ref. A.
2. Read pages 2-33 and 2-34 in Ref. F. Write 100 to 200 words on using a 30-year statewide forecast as the basis for planning a gasoline tax increase next year.
3. Read any one of the reports in Ref. Q.
4. Read pages 4-5 in Ref. S.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Point out that every planning study should result in a report. Economic analysis will be an important part of that report.
	Draw two alternate route lines on the chalkboard between points A and B, and tell the students Line 1 costs 1 million dollars to build and Line 2 costs 2 million.
	Ask the class if this brief comparison of costs is an economic analysis, to see if the students have grasped the idea of coordinated, comprehensive planning.
	After discussing, point out that cost is only part of an economic analysis.
II. Elements of Economic Analysis	Explain that economic analysis is a planning tool and must be tailored to each need. An economic study, like a traffic study, should contain only enough details to accomplish its objectives.
A. Unfeasible route	Sketch on the board three or four alternate route lines, with one through a cemetery and obviously not worth considering.
	Point out that it is a waste of time and money to study an obviously unfeasible route.
B. Economic impact	Emphasize to the students that they are not economists. Therefore, they should rely on the experts for information on the economic impact of a highway plan on an area.
	Ask the students for their ideas on the economic impact a highway might have. (This discussion should bring out the way a new highway location could affect land values, industrial location, new shopping centers, residential development, existing gas stations, motels, etc.)

22237

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Point out that economic impact is only one of the factors considered in comparing alternate routes. But it is one of the most important factors.
C. Construction cost	Explain that public money is scarce and that the highway planner must be concerned about costs.
1. Limited accuracy sufficient	Mention that the cost estimates prepared at this point in the planning do not require great accuracy. Determine whether the students know the reasons for this limited accuracy. Tell them that, first, they are only comparing alternates with the same yardstick. Second, they have no basis for accuracy--they do not have enough information.
2. Designer's costs accurate	Inform the students that the designer will arrive at actual costs by use of plans, specifications, and estimates. Remind them that they are not designing a highway but only comparing alternate routes.
3. Information needed now	For a satisfactory economic analysis, cost information is needed about the road itself and about any structures involved in it. For the road itself, the cost per mile is needed for level terrain, rolling terrain, and mountainous terrain. The cost of structures should be in dollars per square foot; the number of square feet can be based on dimensions of streams and roads scaled from drawings. Explain that the tendency in planning studies is to estimate too low. When retaining walls and ramps are part of the highway, the structure costs should be increased by about 25%.
D. Right-of-way (ROW) costs	Show the class a photogrammetric map with two or three alternate route lines. Have one of the lines pass through developed land and the others through open land.

22238

Supplemental Teaching Aids:

Many good resource books applicable to this unit are available, particularly in the field of special education. Others are the following: Communicating Facts and Ideas in Business, Leland Brown, Prentice-Hall, Englewood Cliffs, N. J., 1961, Business English in Communications, Himstreet, Porter and Maxwell, Prentice-Hall, Englewood Cliffs, N. J. 1964.

A series of three programmed texts by Joseph C. Blementhal are available from Harcourt, Brace, and World. A great deal of free material is available from Western Union including the film "Telegram for America". Pitney-Bowes, Inc. distributes two publications on mailing machines entitled How to Increase the Prestige of Your Mail and 29 Timely Mailing Tips.

Training Time 35-45 hours

2194

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Remind the students that for highway planning, cost figures for acquiring property in the right-of-way need not be exact.
	Ask for suggestions on costing. Point out that an average cost for a gas station or residence is satisfactory.
	Ask the students how they would arrive at these costs. Their answers will show whether they know how their DOT District Offices are organized. The discussion should bring out the fact that the ROW Unit in the District Office has information for making quick property estimates.
E. Benefit to the road user	Write on the chalkboard a user-benefit formula. Explain that the cost of travel time is obtained by averaging a number of estimates.
	Ask the students how much an hour of saving in travel time is worth. Elicit discussion from the class on the reasoning behind the students' thoughts on the value of travel time saved.
1. Example	Work out a typical user-benefit problem on the board.
2. Differences in alternate routes	Tell the class that the user-benefit method takes into account the difference in length of alternate routes. Explain further that all of the alternate routes involve costs of: construction, ROW, maintenance, and travel time.
	Point out that the shortest route does not always have the shortest travel time. Show the diversion curve.
III. Use of Economic Analysis in Highway Planning	
A. New location of road	Display the photogrammetric map with the alternate routes.

CONTENT OUTLINE

1. Steps leading to new location

2. Data from previous ies

3. All factors to be c sidered

TEACHING POINTS AND TECHNIQUES

Review the steps in highway planning discussed previously:

1. Inventory and field scoring
2. Mapping
3. Traffic study
4. Traffic analysis
5. Traffic forecasting

w Point out that an orderly process of highway planning led to the alternate routes on the photogrammetric map.

Assume that in a particular planning study the traffic volume shows a need for improvement of the present road, but the O & D survey shows enough bypassable traffic to warrant a new route.

Also state that the cost of improving on the existing road is excessive.

Remind the students that the full diversion indicated by the curve was not used in assigning traffic to a bypass because not all people follow the theoretical curve.

stud- Point out that the figures which formed the basis for the decision came from the series of studies explained earlier in the course.

Tell the students that the user-benefit method does not always make a clear-cut case for one route over another. Sometimes there is little to choose from between alternates.

Mention that user-benefit is only one more factor to be considered along with the other factors discussed in earlier lessons.

on- A highway planning decision must be based on all pertinent factors, not just one or two.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	State that there is no such thing as only one solution to a problem. Explain that often the traffic study makes only a weak case for a bypass as compared to an existing road location.
a. Political and sociological factors	Tell the students that political or sociological considerations may outweigh economic considerations, as in cases involving relocation of an ethnic group.
	Remind the students that highways cannot be planned with a limited knowledge: all aspects must be evaluated.
IV. Summary	State that this course covers only the elements of planning, but the students can get a broader grasp of transportation planning by reading beyond the required text.
	Mention that this lesson covered only briefly the highlights of economic analysis. It did not consider the social values of accident reduction.

QUESTIONS FOR REVIEW

1. Is the primary purpose for making an economic analysis to help the planner with his work or to convince others of the value of highway development? (Suggested answer: These two purposes are equally important.)

2. What are the principal elements of a simple economic analysis for highway planning?

3. Who should make an economic impact study? How detailed should it be?

4. How do you determine the cost for a rock excavation as compared to an all-earth excavation?

5. Will high ROW costs make an alternate route unfeasible? (Suggested answer: All factors must be considered--not just one.)

6. What circumstances would show that user-benefit calculations to justify the location of an alternate route are not worthwhile? (Suggested answer: Where location is dictated by such things as the

need to preserve scenic or historic areas, or unique agricultural land.)

ASSIGNMENT

1. Read pages 382-392 in Ref. A.
2. Read pages 3-2 and 3-18 in Ref. F. Write 100-200 words giving your views on the State's responsibility to anyone put out of business by a village bypass.
3. Read pages 35-60, 71-82, and 88-92 in Ref. T.
4. Read pages 88-147 in Ref X.

22242

Lesson 10
Geometrics and Design Standards

Winch, D.M. Economics of highway planning. Toronto, Canada. University of Toronto Press. 1963. (Referred to in this unit as "Ref. T")

OBJECTIVES

1. To show the students how design standards vary with traffic volume, type of terrain, and type of area development
2. To acquaint the students with the basic standards used for design of New York State highways
3. To show how geometrics are selected by the highway planner

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Factors Affecting Design Standards	Tell the students that geometric design standards have evolved after years of study and analysis of traffic flow, highway capacities, and highway use. Point out that normal progress requires that we revise standards from time to time to keep abreast of changes. Ask the students to cite a few changes in automobiles in recent years that have influenced geometric standards.

CONTENT OUTLINE

A. Traffic volume

1. Determines design stan

2. Varies with length of designed for

B. Terrain characteristics

TEACHING POINTS AND TECHNIQUES

Examples of such changes are: wider trucks, higher operating speeds, lower cars, increasing marginal friction compelling more access control, etc.

Mention that the highway planner is concerned with providing an adequate facility which will last for the designated length of time. With this aim in mind the planner must also assure that public money is used efficiently to prevent overbuilding or underbuilding.

dard Explain that a road planned for a 20-year forecast of 200 cars a day should obviously be of a lower design standard than a 20,000-vehicle road.

Tell the students that geometric features of a road are designed to suit the forecast traffic. These features include pavement and shoulder widths, curvature, and steepness of grades.

Ask the class why all geometric features are related to traffic volume. The students' answers will show whether they associate traffic volume with operating speed, sight distance, etc.

time Remind the class that the traffic forecast could be for 10, 20, or 30 years, and the requirements could vary substantially for the same road.

Use a hypothetical design-hour and show that designing for a 10-year forecast might require only an R-6 design-class highway. But a design for 20 years might call for an R-5 highway. ("Reference V" explains the various classes of highways.)

Discuss terrain features and their effect on design standards with the class.

After the discussion, remind the students that it is uneconomical to spend

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

a great deal of money on high standards for roads that will have little traffic.

1. Affect design standards

State that even for high traffic volume some concession must be made to the high cost of flattening curves and grades in mountainous terrain.

Explain that motorists expect operating speeds to be lower in mountainous areas. Also, grades for interstate highways are a maximum in these areas.

Point out that steep grades and sharp curves are incorporated in roads throughout the country in mountainous terrain. This applies to New York State also.

C. Developed areas

Tell the class that reduced speed is required in developed areas. Ask the students to give examples of conditions requiring reduced speeds in developed areas. (Examples are: driveways, pedestrians, bicycles, delivery trucks, and other vehicles stopping or standing.)

Explain that the same high design standards are not required for a 40-mph road as for a 60. This is an example of economizing by applying sound planning principles.

State that for developed areas, the slower speeds will not require the long sight distances that high-speed roads require.

Ask the class to cite some effects of sight distances on design. (The answer should bring in: shorter vertical curves, sharper horizontal curves, and steeper grades for crest curves.)

II. New York State Geometric Standards

Inform the students that all states are members of the American Association of State Highway Officials (AASHO) and all

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

help formulate design standards. New York State geometric standards conform to the guidelines of the AASHO. Refer the class to "Reference V."

A. Standards for expressways

Point out that an expressway has approximately twice as much capacity as an ordinary highway. Features such as controlled access, separation of traffic, and elimination of grade intersections give extra capacity.

Write on the chalkboard the capacities of a controlled and an uncontrolled highway of the same width. From these examples illustrate the increase in capacity for roads in U-3, U-4, U-5, R-2, and R-4 design classes.

Explain to the students that in New York State the term *expressway* is used, while in other states *freeway* is used.

Tell the students that the *interstate system* is a system of expressways financed from special funds. Highways in this system are built to a uniform national standard.

Inform the students that the standards already discussed in this lesson do not include *interstate* highway standards. Standards for such highways are described in a different publication of the DOT.

1. Rural expressways

Give each student a copy of Ref. V, the Department's 1959 standards. Review the standards sheet with the class and ask the students to point out which roads have a 70-mph design speed. (The answer: R-1 and R-2.)

Ask why U-1, U-2, and U-3 roads have only a 60-mph speed, to find out if the students realize that these are urban highways, which require lower operating speeds.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Point out that *operating* speeds are usually 10 mph less than *design* speeds.
	Ask the students to compare the capacities of a U-1 road and an R-1 road. Then ask them to give opinions on the difference. After discussion explain that the higher the speed, the greater the required safety; therefore, the lower is the capacity on the high-speed expressways.
2. Urban expressways	Tell the students that urban expressways often create Chinese walls in cities. This type of road cannot accept road crossings approximately every mile as rural expressways commonly do.
	Point out that in cities it is often necessary to maintain local traffic service along with express service. To achieve this we provide service roads (or *frontage roads*) where needed.
	State that traffic generators in cities are usually more closely spaced than in rural areas. Because of this, interchanges must be closer together.
	Remind the students that urban expressways usually have lower design speeds than rural expressways. There are two basic reasons for this: (1) higher ROW costs will not permit the same design standards to be used, and (2) interchanges are closer together, requiring lower speed.
	Ask the class to explain why interchange spacing affects design speed. Their answers will show whether they understand acceleration and deceleration lanes, and weaving and merging traffic.
B. Standards for rural highways	Mention that standards for rural roads merit some attention. Tell the students that the limits on class time

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	prevent the study of the details of each type of highway. Study of the standards sheet, however, will provide some valuable detail.
	Explain that we have two basic reasons for using several types of design. One is to achieve economy; the other is to provide proper service to the highway user. Standards must economically meet forecast traffic.
C. Standards for urban arterials	State that design of urban arterial highways warrants close study because of ROW cost and the special need to provide for parking.
	Ask the students what type of parking they would recommend in place of parking lanes. Discuss *off-street parking* as the solution to the problem of providing adequate parking for an urban arterial highway.
	Explain that urban roads, like rural roads, are designed to meet forecast traffic data.
III. Selection of Geometrics	State that it is the duty of the highway planner--not the highway designer--to select the geometrics.
A. The highway planner selects	Ask the class for the reason that the planner selects the geometrics. The students should know that the designer depends on the traffic forecast of the planner. Retrace the steps leading to the traffic forecast to reaffirm their knowledge as to how the forecast figure was derived.
1. Practice in selecting	Write a few typical DH figures on the chalkboard and ask the students to select a geometric class. (Do not give the type of terrain or the kind of development until a student asks for this information.)
	If students do not ask for additional information, point out that the given

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	information is insufficient. Planners cannot make assumptions but must have factual data for proper selection.
IV. Introduction to Advanced Design Standards	Remind the class that this course is limited to the elements of highway planning. Explain, however, that someday the students may be involved in planning or designing highways for a metropolitan area. Point out that new and progressive thinking must be used on the problems of a large city. Explain that ROW costs are extremely high for urban freeways. With such high costs urban highways may be designed as depressed roads, with air rights reserved for construction of apartment houses or other commercial construction. Inform the class that even the high cost of a tunnel might be justified where property costs and dislocation problems prevent standard treatment. Tell the students that multiple-tiered, elevated highways are a possibility; roof-top roads might also be considered. Mention that the considerations which govern corridor location, route location, and design apply to small rural areas as well as to the large complex metropolitan areas. But the techniques for each area must be tailored to the problem.
V. Summary	Tell the class that there is a great deal of literature on geometric standards and that they should study as much of this material as possible. Explain why DOT personnel, no matter what their present assignment, should have a good knowledge of highway design standards and practice.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

Briefly mention the scope of the next lesson.

QUESTIONS FOR REVIEW

1. What is the basis for the Department's geometric design standards?
2. What are the most important factors affecting design standards?
3. What features distinguish an expressway from any other highway?
4. What features distinguish a *rural* expressway from an *urban* expressway?
5. When are *frontage roads* required?
6. How does a designer decide on the class of highway to build?
7. What determines the spacing of interchanges in the city and in the country?

ASSIGNMENT

1. Read page 15 in Ref. B.
2. Read pages 3-6 in Chapter 23, and Chapters 25, 26, 27, 28, in Ref. I.
3. Read Chapter 1 in Ref. P.
4. Read pages 65-70 in Ref. T.
5. Read Chapters 4 and 5 in Ref. U. Write 100 to 200 words giving your views on separate geometric standards for warm climates and cold climates.
6. Study Ref. V.

7. What elements should be included in a route-location report?

8. How long should an effective route-study report be?

ASSIGNMENT

1. Read pages 432-437 and 443-452 in Ref. A.

2. Read pages 5-6 to 5-62 in Ref. F. Write 100-200 words explaining what you would do as a location engineer if a recommended westerly bypass went through a swamp, and the second choice, an easterly bypass, went through a housing development.

OBJECTIVES

1. To acquaint the students with Federal and State programs for highway safety
2. To acquaint the class with the Department of Transportation procedures for implementing the State safety program
3. To inform the students of safety measures such as pavement striping, signing, signals and others

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Accent on Safety	Explain that this lesson is primarily concerned with highway safety. Tell the students that the annual *death toll* on the nation's highways is approaching the 60,000 mark. Many agencies are concerned and alarmed at the high loss of life. As highway planners we must design our highways to be as *safe* as possible.
A. The Federal safety program	Explain that a Federal safety program existed but was given added impetus by President Johnson. Legislation relating to highway safety was strengthened and Congress enacted additional laws. Read to the class excerpts from Section 402 of Ref. E. Point out to students that Section 402 relates only to the driver and the road, not the vehicle. Safety standards for cars are covered under separate Federal legislation.
B. The New York State program for highway safety	Tell the class that the State legislature became increasingly concerned with the rising State death tolls. In consonance with Federal legislation, a *State Highway Safety Program* was approved. State that the concern for highway safety is so universal that it is not necessary to mandate local safety programs. As a minimum service, State agencies provide guidance and coordination to local agencies to promote safety.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Tell the students that the present highway law is being recodified. The changes will make the law more useful to the DOT in its operations.
B. Law often confusing: 1. A route description	Show the class how confusing the present law is by reading a route description from Section 340 of Ref. C. Ask the students if they can find the described routes on a map. Trace one of these routes on an oil company map. We can readily see that route numbers in Section 340 have no relation to the route numbers we see posted on highways. Discuss Articles XII-A and XII-B. These sections show how a facility such as an expressway gets it start in the legislature.
C. Many changes made in law 1. Route changes	Point out that every time a route location is changed a new law must be passed. The change in the law revises the legal description of the route.
2. Location changes	Read excerpts to the class from Section 30, paragraph 1, of Ref. C. This section establishes procedures for making these changes. Special enabling legislation is usually required for new highway locations and reconstruction projects. In some cases, however, approval by the county board of supervisors is enough.
3. Abandonment of a highway	Discuss abandonment of highway facilities. This type of action also requires legislation when tied into new highway locations. Official abandonment orders of the DOT and of a county or town are based on authority granted by the State highway laws. Explain that the DOT, like any other public agency, cannot spend money without legal authority.
IV. Other Laws Related to Highways	Tell the class that the legislature passes many laws. Some of these affect the DOT but are not highway laws.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. State laws	Read excerpts to the class from Chapter 620 of Ref. C. This chapter shows that the *Executive Law* was revised to institute a highway safety program. Ask for opinions as to why the highway law itself was not amended to include the safety program. The students should realize that it was necessary to broaden the Governor's powers before the safety program could be started. Read excerpts aloud from Chapter 687 of Ref. C. This chapter shows that it was necessary to pass a *special law* to control junkyards and automobile graveyards. This is another example of the need for new legal authority for work not covered by other legislation.
B. Federal laws 1. To provide safety	Point out that *Federal safety legislation* also places a requirement on each state. The Federal Act, (Section 402 of Ref. E) requires the Governor of each state to carry out the provisions of the law.
2. To require planning	Discuss Section 134 of Ref. D. This section shows how the Federal requirement for comprehensive planning affects the State highway program. Section 134 applies to urban areas having more than 50,000 population. These areas cannot receive Federal funds until the provisions of this section are met. Ask the class at what stage of design they would try to meet the requirements of Section 134. The students' replies should cover a range from the earliest design stage up to contract plans. Write the range of answers on the chalkboard. Point out that Section 134 requires submission of a planning report to the *urban area planning group*. We must often obtain approval from this plan-

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	ning body before Federal consideration is given. Any design effort on our part before approval by the Government would be premature and wasteful.
V. Value of the Law to DOT	Ask for opinions as to specific authority granted by the laws which aids the DOT in planning and design of highways.
A. Authority granted to DOT	Write acceptable answers on the chalkboard. Add the following as necessary to complete the list:
1. To survey	1. The right given the DOT to make surveys, borings, and soil tests on private property
2. To remove encroachments	2. The right to remove encroachments from the ROW, such as trees and billboards
3. To provide access	3. The right to provide access to a public highway for a parcel of land which has none
4. To remove abandoned cars	4. The right to remove abandoned or disabled vehicles from the ROW if they are a hazard to the traveling public
5. To limit access	5. The right to limit access from a driveway to a State highway and to specify the detailed design of the access; the right to curb the road for drainage; and the right to limit access to such areas as shopping centers, gas stations, and other businesses
VI. Summary A. Importance of Highway law	Point out that the DOT receives many benefits from the highway laws. This lesson covers only a few; there are many others. Explain to the students that later in their careers they will find knowledge of the laws of tremendous value.
1. Many legal actions needed	State that higher level DOT personnel are involved in other legal actions.

UNIT V (14.0406-05)

RECEPTION AND TELEPHONE

Performance Objectives:

Upon completion of this unit the student will be able to demonstrate to the satisfaction of the instructor her mastery of the following: various types of telephone equipment for conference, sequence, toll call, etc., office forms associated with telephone usage, effective telephone techniques, handling of office callers and appointment records.

Unit Outline:

A. Basic Telephone Information

1. Types of telephone calls
2. Effect of time zones
3. Types of equipment
4. Directories
5. Special telephone services

B. Development of an Attractive Telephone Voice

1. Element of speech
2. Attitudes

C. Handling Calls

1. Incoming calls
2. Outgoing calls

D. Telephone Records

1. Itemized accounting of toll calls and charges
2. Recording conversations
3. Frequently called numbers

E. Receiving Office Visitors

1. Appointments
2. Unexpected callers

2195

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Use of photogrammetric maps	Tell the class that once a corridor has been selected it is possible to obtain photogrammetric maps covering the proposed route. Ask the class whether these maps should be prepared for the planning study. The answers you receive will tell you whether the class remembers that the details of contours and a 200' scale are needless refinements for a planning study.
C. Use of reconnaissance	State that there is no substitute for a field reconnaissance, whether it is made on foot, by car, or from the air. Point out that after trial lines have been plotted on a photogrammetric map, the next step is to make a field inspection. Explain that the alternates now being considered are *not* the alternates considered in the planning study. The present ones are alternate routes within the same corridor. A route location will be chosen from them on the basis of engineering factors--not social impact or other factors. Ask the students what they would look for on a field inspection. (Suggested answer: Soils, drainage, structures, excavation, and other design features.)
1. Construction problems	Mention that valuable effort and money can be saved on a location study by avoiding a route which is clearly unfeasible because of such conditions as swamp, deep muck, or rock. Point out that only one location may be feasible in a corridor, simply because of construction problems. Or there may be several feasible locations.
2. ROW costs	State that some locations may be quickly dropped as unfeasible because of excessive ROW costs.

22255

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Mention that the planning study does not consider more than general costs. The preliminary engineering study, however, must make an exact determination of costs.
D. User-benefit analysis	Ask the students if a user-benefit analysis is necessary in a route location study.
	After their comments, point out that such an analysis is definitely useful in route location. This analysis is a straightforward comparison of user costs without the intangibles of impact, development, social, and community values.
	Explain that intangible elements were considered in selecting the *corridor*. The only remaining problem is to define the best and cheapest route that will give the traffic service needed, as shown by the planning study.
E. Revision of economic analysis	Tell the students that in some cases it may be necessary to retrace the planning study to make a revision in the corridor.
	Ask the class when a revision may be necessary. The students should recognize that one answer to the question is the following: The situation where the selected corridor is unfeasible because of construction or ROW costs.
	Point out that the location engineer should consult the highway planner in such a case, and not arbitrarily change to another corridor, himself.
F. Route-location report	Repeat that the preliminary engineering study usually fixes the final line and grades.
	Mention that the preliminary plan is the one presented at public hearings in which the selected location must be justified to the public.

22256

CONTENT OUTLINE

IV. Summary

QUESTIONS FOR REVIEW

1. What is the fundamental
   preliminary engineering
2. How wide is a corridor
3. What type of map is best
   the best scale to use?
4. What is the basis for se
   route costs?
5. How large an area should
   location study?
6. Should a field inspectio
   are started?

TEACHING POINTS AND TECHNIQUES

Explain that it is not enough to work out two or more alternates and just select one as the best. Point out that the alternate lines, grades, costs, and other elements should be included in a route-study report, similar to the planning study.

Remind the students there is no substitute for a thorough, factual engineering presentation.

State that first the DOT must be satisfied it is getting the best report, and second, the public must be satisfied. Point out that a report has no set length.

Briefly highlight the difference between highway planning and highway engineering.

Explain that a planning comparison of alternate routes really is a comparison of alternate corridors represented b single routes.

Point out that comparison of two routes (which provide approximately equal traffic service in a single corridor) is done in the engineering phase.

difference between highway planning and
?

and what defines its limits?

t suited for a route-location study? What is

l be covered by photogrammetry for a route-

on be made before or after the contract plans

22257

7. What elements should be included in a route-location report?

8. How long should an effective route-study report be?

ASSIGNMENT

1. Read pages 432-437 and 443-452 in Ref. A.

2. Read pages 5-6 to 5-62 in Ref. F. Write 100-200 words explaining what you would do as a location engineer if a recommended westerly bypass went through a swamp, and the second choice, an easterly bypass, went through a housing development.

22258

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Preliminary engineering, can also be financed partly from Federal funds (but only from regular highway funds). At the option of the state, however, it can be financed completely from state funds.
	NOTE: The highway planning research funds consist of $1\frac{1}{2}\%$ of the total of Federal highway funds.
A. Determining the corridor	Explain that there is no definite width to a corridor. Mount a USGS sheet on the chalkboard and draw a line along a valley to illustrate one type of corridor.
	Mount another USGS sheet on the board showing a city, and draw a line down a street to show another type of corridor.
	Ask the students for their ideas on the criteria which determine a corridor.
	Conduct a discussion and then explain that the highway planner considers *traffic service* as the key element in defining a corridor.
	Point out that one corridor could provide vastly different traffic service from an adjacent corridor. Explain that one corridor might carry bypassable traffic around a village; another corridor might bypass the village and also serve a second community.
	Mention that the highway planner compares alternate corridors using all the factors taught in the course.
	Remind the class that the costs used in the study are limited to estimates per mile. The planner is not concerned with the cost of individual design features, except in a general way.
	Use the USGS map on which you previously drew a valley corridor and draw a second

22252

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	line next to the first one. Explain that the alternate line is really an alternate corridor.
	Ask for comments on the second line to see if the class understands that a planner would not need to consider alternate routes in the same corridor. Planning alternate routes is part of preliminary engineering, the next phase of work after highway planning.
B. Determining the route	Tell the class that a route is mainly the line a road will follow.
	Point out that preliminary engineering does not require the same detail as *final design*. Usually route location is accurate and only minor adjustments are made when the contract plans are drawn, in the final design phase.
	Refer to the two alternate lines in the valley, (drawn on the previous map) and ask the class which one they would select.
	The discussion should bring the answer that no decision can be reached from merely looking at a map with a scale of 1" = 1 mile. Point out, also, that a USGS sheet is *not* the right tool for preliminary engineering.
	Remind the students that different types and phases of planning require different methods and procedures.
	Ask what would be the proper type of map for a *route location* study. (Answer: Photogrammetric at 1" = 200'.)
II. How to Select the Corridor	Briefly review the steps which lead to the selection of a traffic corridor. (The steps are: road inventory, traffic study, traffic analysis, traffic forecasting, and economic analysis.)
	Remind the students that a highway planning study is the basis for ex-

22253

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	penditures and must be based on facts.
	Tell the class that a planning-study report should include all information needed to back up the choice of a particular corridor. This report is the end-product of the planning study.
III. How to Determine the Route Location	Point out that the preliminary engineering phase follows the highway planning phase.
	State that the route-location study is part of the preliminary engineering phase. In this study, the route is determined within the traffic corridor defined by the highway planning study.
	Mention that the geometrics of the route are fixed by the traffic forecast.
A. Review of the route-study	Ask the students why the location engineer should review the route-study report.
	Indicate that it is always helpful to know the background of the problem. Mention in particular that a knowledge of the traffic, the economics, and the land-use could help the designer when he has two apparently equal routes to choose between.
	Remind the class that the designer should not be required to repeat any of the highway planner's work. Unless the report is well prepared, however, there will be much needless investigation of such factors as location and traffic for proposed interchanges.
	Emphasize that a route-location study is basically a straightforward problem in engineering design. Point out, however, that this is true only if the designer can limit his study to the selected corridor, and also has all the necessary data.

22254

Lesson 11
Route Location

REFERENCES CITED IN THIS LESSON

Hay, W.W. Introduction to transportation engineering. New York. John Wiley. 1961. (Referred to in this unit as "Ref. A")

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill. 1960. (Referred to in this unit as "Ref. F")

OBJECTIVES

1. To explain the basic differences between highway planning and preliminary engineering, as they affect route location
2. To review the principal elements of route location in small cities, as for a village bypass

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Differences Between Highway Planning and *Preliminary Engineering*	State that it is important to know the difference between highway planning and *preliminary engineering*, especially for route location. Ask the students to explain the difference to determine if they understand the principle of lowest level of required effort. If proper answers are not given, explain that the highway planner will not be concerned with line, grade, drainage, and other design details. He is concerned only with determining a *corridor* or general route location. Point out that another difference between highway planning and preliminary engineering is in the method of financing. Highway planning studies are financed partly from Federal Highway Planning Research (HPR) funds and partly from state funds. (The amounts from each are in the ratio of about 2 to 1.)

MICROCOPY RESOLUTION
NATIONAL BUREAU OF STAN

TEST CHART
NDARDS-1963-A

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
II. The DOT Safety Crusade	Relate to the students that the DOT is conducting a *safety crusade*. The object of this campaign is to reduce highway accidents and deaths. On the chalkboard write three headings: Driver, Vehicle, Road. Ask each student in turn to write weights for each, reflecting safety importance, and adding up to 100 percent. Conduct a class discussion on the safety poll. Ask for suggestions on how to achieve safety improvements on the state highway system. Write suggestions on the chalkboard for reference during this lesson.
A. Updating safety standards	Read excerpts from Refs. AA, BB, and CC. These documents will acquaint the students with the nature of the *safety standards* revisions. Point out that the intent of the revised standards is to permit *safe recovery* when a vehicle is out of control. State that there are numerous causes of vehicle accidents. Two causes are driver error and machine failure. Considering only these factors we must make highways as safe as possible. Explain that safety considerations take precedence over the concept of beautification. For example, trees are potential hazards. Highway beauty can be attained but plantings must be at safe clearances. Tell the class that 3114 persons were killed on highways in New York State in 1968 and 355,799 were injured. These drastic figures emphasize that highway engineers have an obligation to the public. We must provide the driver every possible highway safety feature. In highway planning nothing has a higher priority than the safety program.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Review the students' suggestions for safety improvements previously written on the chalkboard. Compare the suggestions with the points contained in Ref. CC. Ask for additional items to add to standards revision.
B. Spot improvements of unsafe conditions	State that the safety improvements mentioned above are limited to some of the problem areas on the State highway system. Point out that there are many dangerous conditions which can be corrected with minor effort. This type of effort falls into the category of *spot improvement*. Safety improvements under this category can be accomplished without resorting to extensive programs. Write on the chalkboard the 14 types of improvements listed in Ref. DD. Ask each student to comment on the relative hazard priority of each improvement. Compare comments to determine the extent of agreement on highway hazards. Explain that priorities have not been established for the 14 types of improvements. Sufficient data is not available to correlate Federal and State highway system deficiencies.
III. Standard Safety Measures	Inform the students that experience has brought establishment of a set of standard safety measures. For example the DOT *pavement markings* and other driver aids are parts of the standard measures.
A. Road markings	Striping and other road markings are simple and effective means for safety control. Ask for comments on the use of *yellow striping* to designate "no passing." Point out that the traditional double lines, broken lines, and combination of broken and solid lines are still

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	standard. Explain further that the yellow line, used to denote a barrier to passing, alerts a driver immediately to a dangerous passing situation. Ask for comments on the practice in some states of also posting "No Passing" signs at the beginning of each restricted section. Poll the students to determine whether the class would recommend that this practice be followed by the DOT. Point out that *edge striping* is just as important as centerline or lane striping. This practice helps drivers at night, and during rain or fog. Ask the students what they consider to be a safe sight distance for passing. Inform the students that a distance of 1500 feet is desirable without striping, and 600-800 feet is acceptable with a striped road. Tell the class that pavement markings are detailed in Ref. W. This Manual is based on national standards, developed through agreement among all the states. Inform the students that two important fields in highway planning are *traffic* and *safety*. Ref. W is an invaluable aid for students interested in these fields as careers.
B. Signs for safety	State that the proper selection and installation of signs is a recognized safety measure. Ask the class if they know the types of signs by function. They are: a. Regulatory--used to control speed for stops and traffic movement b. Warning--for approaching curves, intersections, and impending hazards c. Information--used to designate

F. The Receptionist Area

1. Order and attractiveness
2. Reading materials
3. Cleaning services

G. Managing Appointments and Appointment Record-Keeping

1. Maintaining desk calendars
2. Caller's register
3. Updating card file of visitors
4. Planning meetings and appointments
5. Easing employer's burden

Supplemental Teaching Aids:

The telephone company will often provide resource people as well as free materials for this unit.

Two very good resource books are Clerical Office Practice by Agnew and Meehan, South-Western, 1961 and General Office Practice by Archer, Brecker and Frakes, McGraw-Hill, New York, 1963.

The telephone company utilizes teletrainer equipment which is accompanied by scripts which are quite useful.

Training Time 15-25 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	route numbers, identify towns, and provide other data
	Explain that sign standards for size, shape, color, reflection, etc., are the result of years of development. These features, which are nationally standardized, assist the highway user as he travels throughout the country.
	State that drivers must be alerted at decision points on highways. These points are at intersections, interchanges and other critical points. We must alert drivers to such factors as speed changes, lane changes, and other maneuvers. Every indecision on the part of a driver could cause an accident.
	Ask the students for their views on color coding in complex signing areas. An example of such an area includes intersections of 5 or 6 numbered routes within a short distance.
	Draw on the chalkboard a typical complex of intersections and numbered routes. Illustrate how color coding could help a driver trace a specific route through a maze of route numbers and turns.
	Tell the students that this concept is similar to the trail blazer idea leading to the toll roads such as the Thruway. Color coding may be a standard practice in the future.
C. Traffic signals and devices	Explain that pavement markings and signs are only part of the program for highway safety. *Signals* represent an equally important element for safe traffic control.
	Ask each student to list the different types of signals on a sheet of paper. Write answers on the chalkboard. Fill in any missing types so that the full family of devices will be listed on the board. These are:

22264

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	a. Fixed-time (preset time) b. Semi-actuated c. Fully actuated d. Progressive
	Point out that there are many devices for detecting traffic, such as radar, ultrasonic, loops, infrared, electric eye, treadles, etc. These devices send impulses to controllers which regulate traffic safety.
	State that *controllers* can be operated by radio, electronically from a computer, by programming a master controller, or by other means.
	Explain that signal installations have become very sophisticated to keep up with increasing traffic demands. Each student can strengthen his technical knowledge by studying various books on traffic signals and devices.
IV. Summary	Repeat the 1968 accident statistics for New York State--3114 killed, 355,799 injured.
	Repeat that safety is the concern of every branch of the DOT and of each student.
	State that the DOT can do nothing about improving the driver or the vehicle. But every effort can be made to provide safer highways.
	Briefly mention the scope of the next lesson.

QUESTIONS FOR REVIEW

1. What critical condition has stimulated the intensive campaign for highway safety?

2. What is being done about safety on the national level? On the State level?

3. What changes in standards is the DOT making to provide safer highways?

22265

4. What is the most desirable type of spot improvement to make from the viewpoint of accident reduction?

5. What are the principal traffic control devices?

6. What is color coding?

7. What are the principal types of traffic signals, by function?

8. What determines which type of signal should be used for a specific situation?

ASSIGNMENT

1. Read pages 248, 281, and 282 in Ref. A.

2. Read Chapter 620 in Ref. C.

3. Read section 402 in Ref. E.

4. Read pages 22-5, 22-41, and 22-42 in Ref. F. Write 100 to 200 words stating what a highway designer can do to provide safer highways.

5. Read Chapter 1, Introduction, and Chapters 2, 3, 4, 10, and 20 in Ref. I.

6. Read the article "Monitoring Traffic Speed and Volume," in Ref. N.

7. Read pages 82-88 in Ref. T.

Lesson 13
Highway Law

REFERENCES CITED IN THIS LESSON

New York Highway Law. Sections 3, 10, 30, 340, 341, 343 and 349C, D, E, and F. (Referred to in this unit as "Ref. C")

United States Federal Aid Highway Act of 1962, Public law 87-866. Section 134. (Referred to in this unit as "Ref. D")

United States Highway Safety Act of 1966, Public law 89-564. Section 402. (Referred to in this unit as "Ref. E")

OBJECTIVES

1. To acquaint the students with the New York State laws and with other State and Federal laws about highways
2. To show how a knowledge of these laws will help employees carry out the functions of the Department of Transportation

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. The New York State Highway Law	Tell the class that many of the laws passed each year by the legislature apply to the State highways.
A. DOT created by law	Explain that the *Department of Transportation* was created by an act of the legislature and operates under authority granted by law. Remind the class that the functions of the former Department of Public Works have been transferred to the new Department of Transportation. All laws previously relating to the DPW now apply to the DOT.
B. Knowledge of law needed by DOT employees	Explain that the Department of Transportation has a *legal staff* to handle all matters pertaining to the law. A brief introduction to highway laws and the lawmaking process will be beneficial to the student.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Reviewed by department	Tell the class that all local bills are referred to the appropriate State department for review. Explain that the Governor usually relies on the advice of his cabinet members when acting on approved bills.
2. Steps in review	Write on the chalkboard the steps taken by the Department of Transportation in reviewing a local bill. These are: 1. The DOT receives the bill from the Governor's Counsel. 2. DOT staff elements review the bill. This usually includes the following elements: a. Chief engineer b. Deputy chiefs c. Operation and Maintenance unit d. ROW Unit e. Planning and Programming group f. Other elements 3. The DOT Counsel together with the rest of the DOT staff makes one set of recommendations. 4. The DOT sends the recommendations to the Governor's Counsel.
III. Details of the Highway Law	Write on the chalkboard the title of the articles (I thru XII-B) in the highway law which affect the day-to-day workings of the DOT. Briefly explain each, to show the class how the Department gets its authority to design, construct, and maintain highways and bridges.
A. Court interpretations sometimes needed	Point out that most laws are written in general language. Interpretations by the courts are sometimes necessary to clarify particular questions. Explain that the intent of the laws is not a matter for engineers to decide. This is done by the DOT Counsel.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
II. The Lawmaking Process	Inform the class that there is a formal procedure for changing the laws of the State. Point out that sometimes the legislative process is slow and combersome. Laws are not passed in haste because the *health, safety, and welfare* of the public are at stake.
A. Department of Transportation bills	Explain that the basic highway law of New York has been comulatively enacted over many years. This process started when New York State first recognized the need for special highway laws. As progress in transportation is made and problems arise, we must also adjust the laws.
1. Reasons for changes in laws	Ask the students if they can state the legal reasons for changes in the laws. The class should understand that new locations, arterial route revisions, and many other changes require *special legislation*.
2. Early steps for Department bill	Inform the students that all State department heads are members of the Governor's cabinet. Therefore, any department bill is a *Governor's bill*. The early steps for getting a bill passed are: a. Drafting of a bill by the DOT b. Submitting of bill to Governor's office for review and approval by Budget Bureau and Governor's Counsel c. Introduction of bill in legislature as a Governor's bill
B. Local bills	Point out that many senators and assemblymen introduce bills relating to State highways. These are often introduced on behalf of some local group with a special interest.

22268

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Some of these are: property taking, quit-claiming, replacement in kind, system mileage, legal limitations, archeological and historical salvage, flight-path clearance, air and water pollution, and air rights.
2. Knowledge of law needed by students, too	Remind the class that they are not lawyers and need not try to do the work of lawyers. But a good knowledge of highway law will promote better public relations and help protect both State and private property.
	Briefly mention the scope of the next lesson.

QUESTIONS FOR REVIEW

1. What is a Department bill and how is it introduced in the legislature?
2. Who reviews a local bill?
3. What is the basic difference between Sections 340 and 341 of the Highway Law?
4. If a reconstruction contract includes 2.0 miles of new location broken into three pieces of different lengths, what procedures are required to authorize it?
5. By what authority does the DOT take property for road construction?
6. Who is responsible for the State highway safety program?
7. Who must approve the design of an arterial highway in Yonkers? In Buffalo? In Glens Falls?
8. Of what use is knowledge of the highway law to a senior engineering technician in the Soils Lab?

ASSIGNMENT

1. Read Articles I-IV in Ref. C. Write 100 to 200 words expressing your opinion of how the Highway Law should be recodified to simply it.

Lesson 14
Highway Finance

REFERENCES CITED IN THIS LESSON

Hay, W.W. Introduction to transportation engineering. New York. John Wiley. 1961. (Referred to in this unit as "Ref. A")

National Highway Users' Conference. Federal aid for highways; revised edition. The Conference, Washington, D.C. 1959. Includes a supplement dated 1961. (Referred to in this unit as "Ref. B")

Traffic Quarterly. The Eno Foundation for Traffic Control, Saugatuck, Conn. (Referred to in this unit as "Ref. N")

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill. 1960. (Referred to in this unit as "Ref. F")

OBJECTIVES

1. To acquaint the class with various methods of financing highway construction
2. To review current highway financing practices in New York State
3. To show how a knowledge of financing will help the students in their jobs as planners or engineers

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Philosophy of Highway Financing	Remind the students that the State of New York has an extensive highway program estimated to cost many millions of dollars. Tell the students that there are several schools of thought about the proper way to finance highway construction. Basically, there are two concepts that predominate in financing.
A. Pay as you go	Ask the class for opinions on the concept of building highways that can be paid for from current revenues. Point out that this method would relieve the State of long-term debt but would result in fewer miles of highways being built annually. We must realize that ready cash is available only in limited amounts.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Emphasize that in making financing decisions, as in engineering decisions, it is necessary to have all the facts before forming judgments.
II. Methods of Financing New York State Highways	Repeat that there are many methods of raising money to construct highways and that there is no one method which is superior to others. Remind the students that finance problems are like design problems and the solutions must be tailor-made to fit the needs of the particular government agency involved.
A. Financing for free (non-toll) roads	Ask the students if they know whether all roads in New York State are *free roads* and list on the chalkboard the roads that the students say are not free. Assuming that the only toll road cited is the Thruway, ask for comments on the various toll bridges, tunnels and highways such as the Southern State Parkway and Whiteface Mountain Road. Determine from the comments if the class considers these roads as toll roads, when the only access to a portion is through a toll facility. Point out that a road is considered a free road up to the point of the last free access. Explain that there are numerous sources of finance for free roads.
1. Gas tax revenue	Elicit from the class the amount of gas tax charged by New York State and by the Federal government. Tell the students that some states earmark gas tax revenues for highways only, but in New York State the money goes to the general fund. Mention that in New York State the

22276

UNIT VI (14.0406-06)

SOURCES OF INFORMATION

Performance Objectives:

Upon completion of this unit the student will be able to demonstrate her knowledge of information sources by compiling a list of information to meet specifications designated by the instructor.

Unit Outlines:

A. Reference Books as a Tool of the Office Worker

1. Importance of accurate business information
2. Kinds of information needed
3. Necessity of obtaining information quickly
4. Necessity for initiative in finding information

B. Reference Books of the Office Worker

1. Dictionaries
2. Reference manual for stenographers and typists
3. English grammar and style books
4. Directories
5. Thesaurus

C. Other Sources of Factual Information

Supplemental Teaching Aids:

The most obvious resource person is of course the librarian. Also available is the Gregg Secretarial Record #6, Set #2 Finding Needed Information. The film "Look It Up-Dictionary Habits" (11 min.) is available from Cornet Instructional Films.

Training Time 3-5 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	general fund provides for highways *and* other needs.
2. Motor vehicle fees	Point out that vehicle registration fees and operator license fees yield additional revenue which goes to the general fund. Some states also earmark these funds only for highways.
3. Bond issues	Refer to the earlier discussion of the philosophy of financing and tell the class that New York State has had numerous bond issues for highway financing. Mention that highway bond money can be spent on highways only. Ask for comments on the difference between crediting the general fund with user taxes and diverting special purpose funds which cannot be used for general purposes. Explain that a bond issue for any special purpose is like a trust fund and cannot be diverted.
4. Sales tax and income tax	Tell the students that the State sales tax and income tax also go to the general fund. Therefore, in one sense these taxes are another method of financing highway construction.
B. Financing for toll roads	Ask the class why toll roads are necessary and what are the alternatives to charging tolls on roads. Point out that in principle there should be no toll roads, but in practice we have the choice between charging tolls or having no road at all for many years. Remind the students that motorists who pay tolls have made a decision that their time plus the lower exposure to accidents are worth the toll they pay.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Interstate roads	Ask the class if any toll roads can be on the Interstate System. Mount a highway condition map on the chalkboard and trace Interstate 87 to show how part is free and part is toll. Repeat for Interstate 90 in the Albany area, to show that part of the Berkshire Thruway is on the Interstate System and part is not. Explain that the Federal government is inconsistent in its toll road policy because there is not enough money in the highway trust fund to buy up the toll bonds and make these sections free. In New York State alone it would take a billion dollars to pay for the Thruway. Ask the students for comments on what should be done about the toll parts of the Interstate System. Tell the class that when its toll bonds have been retired, any toll road can become free. State that the legislation which created the toll authority usually spelled out what would happen to the toll status after the bonds were paid off.
2. Other types of roads	Mention again that all toll roads are not on the Interstate System. Refer to the earlier part of the lesson and remind the students that there are other toll facilities in New York State in addition to the Thruway. Refer to the condition map again and review the portions of the Thruway that are not classified as being in the Interstate System. Ask the class to discuss Federal-aid financing of interstate roads. Trace the free parts of the Interstate 87 and Interstate 90 on the map and mention

22278

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	that the State received Federal financing for these portions.
	Explain that the Federal government would not approve the Southern Tier Expressway as an interstate highway because it was planned as a parallel route to the Thruway. The 90-percent Federal support money can be spent on only one of two parallel roads.
	Remind the class that no support money was provided for the Thruway, either. New York State has been trying for years to recover the money spent on this road from the Federal government.
III. Refunds and Assistance	Ask the students if all the gas tax and other user funds go to the general fund or if any is diverted.
	Explain that in New York State there is an extensive program of state aid for highways. Cities, counties, and towns receive financial assistance to help pay for the cost of local highway programs.
	Point out that the arterial program is basically a local financial aid program. ROW costs are paid in full by the State; construction costs are provided in equal amounts by State and Federal governments.
IV. DOT 1968 Program	Ask the class to estimate how much the Department spent in 1968 on highways and write the estimates on the chalkboard.
	Tell the class that the 1968 Annual Report shows $450 million for construction and $64 million for maintenance
	Point out that the construction work included both new highways and reconstruction. The funds came from three sources: 1. Bond issue money, balance from earlier years

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

Briefly mention the scope of the next lesson.

QUESTIONS FOR REVIEW

1. What are the usual methods of financing governmental spending?
2. What is meant by diversion?
3. What determines the limits of a toll road?
4. What highway user taxes are levied in New York State?
5. If a highway bond issue is passed by the Legislature and approved at a referendum, what percentage of the money can be used for highway maintenance?
6. What percentage of an interstate highway system is allowed to be toll road?
7. New York City has a city tax on gasoline. How do other cities and counties obtain money for highways?
8. Of what value is a knowledge of highway financing to a designer?

ASSIGNMENT

1. Read pages 393-403 in Reference A.
2. Read pages 9-14 in Reference B.
3. Read pages 1-5 thru 1-56 in Reference F. Write 100 to 200 words giving your views on allocating road user funds such as gas tax.
4. Read the article "Financing Highways Now and in the Future," in the October 1956 issue of Reference N.
5. Read the article "Financing a Highway Program," in the October 1959 issue of Reference N.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	2. General funds appropriations 3. Federal aid Emphasize that decisions on methods of financing are fiscal problems, not engineering problems.
V. Uses of Financing Knowledge	Explain that both planners and designers should know the financial resources of the State. Ask the class why a knowledge of financing is important. Determine if the students grasp the principle of not producing elaborate plans or designs which cannot be implemented because of funding limits. Tell the class that *stage construction* is an answer to financial limitations, and provision for future highway lanes in the median is an application. Another answer to financial limitations would be to plan a new route 100 miles in length, but to provide for building it in five sections. All of the sections would be beneficial for several years and ultimately would be connected to provide a whole new route. Tell the class that it is not good practice to plan or design against a limit of dollars, but *knowing* the limit results in *more realistic* planning and designing.
VI. Summary	A broad knowledge of highways will help the highway engineer do a better job. Highways are financed from various sources, and maximum return must be obtained for the dollar. Financial planning by Federal and State governments covers the same type of problems that an individual encounters.

Lesson 15
Introduction to Urban Transportation Planning

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill. 1960. (Referred to in this unit as "Ref. F")

OBJECTIVES

1. To introduce the students to transportation planning for urban areas
2. To review the previous 14 lessons and offer the students a program for continuing study at home

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Evolution of Urban Transportation Planning	Tell the class that urban transportation planning developed out of the need to analyze and design the complex highways of today and tomorrow.
A. Finding minimum traveltime	Mount a city map on the chalkboard and point out that large cities have hundreds of miles of streets. On the map pick any street intersection and call it Point A. Then locate another point 4 blocks east and 4 blocks south of A; call it Point B.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Show that there are about 40 possible routes for going from Point A to Point B. Ask the students how they would select the route of minimum traveltime from these 40 choices.
B. Method of finding it 1. Manual methods not feasible	Point out that there may be literally thousands of alternate paths for travel across an entire city and it would be impossible to select minimum paths by manual means. Explain that the sheer bulk of data to be analyzed forced the development of special tools to do the job.
2. Mathematical methods developed	Tell the class that procedures have been developed for finding paths of minimum traveltime by mathematical techniques. Each subsequent transportation study improved and refined the process as better and faster computers become available.
a. Computer used	State that a typical problem might be to determine the minimum path from a point to approximately 3,000 other points. Solving problems of this kind is not feasible without a computer.
II. Mathematical Models	Tell the class that there are a number of theories about the best way to make traffic assignments in complex urban areas.
A. Terminology	Explain that no one theory has been proven superior, but it will be helpful to briefly discuss the principal techniques and to learn some of the terminology. The terms used include the following: 1. Node--a point designating a highway intersection or zone centroid 2. Link--a portion of a highway connecting two nodes 3. Route--a group of connected links;

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	the shortest route in time is the minimum time path. 4.Tree--all the minimum time paths from one node to all other nodes.
B. Gravity model	Point out that as far back as the 1920's, it was reasoned that a model from Newton's law of gravity could be used for determining intercity travel flows. Explain that research and study is still continuing to improve the accuracy of the gravity model. The original Newton formula has been modified to account for the purpose of each trip and other factors which influence travel patterns.
C. Intervening opportunities model	Tell the students that the *intervening opportunities model* is based on the principle that people tend to travel minimum time paths. This mathematical model states: the probability of a trip originating in one zone finding a destination in another zone is proportional to the possible trip destinations in the other zone. Further, the proportion takes into account the number of trip origins which have not found a closer destination. Point out that this model is different from the gravity model because it is based on distribution of trips made to near or far destinations of similar characteristics, regardless of the size of the zones (mass). The gravity model, however, is not based on attraction of masses proportional to size and distance.
D. Competing opportunities model	Explain that the *competing opportunities model* is not based on either the relative mass or relative distance of traffic zones, but on relative traveltime.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Tell the class that this model states: the probability of a trip that originates in one zone, finding a destination in another zone is the ratio of the trip destinations in the other zone to the total trip destinations between the zone of origin and the same time band which contains the zone of destination.
E. Special purpose models	State that some studies go into greater depth because of special considerations such as mass transit. Mention that models have been developed to estimate what percentage of trips will use private transportation and what percentage will use public transit. Inform the group that models have also been constructed to allocate trips solely by *land use* (allocation of trip ends). Summarize by pointing out that all the models already developed and to be developed are special tools to quickly process huge quantities of data.
III. Fundamentals of Urban Transportation Planning	Mention that the basic principles of urban transportation planning were learned earlier in this unit. Point out that the two basic principles for small rural areas also apply to urban transportation planning: 1. Is a new road necessary 2. Where should a new road be located? Point out that road requirements for cities are very complicated and, therefore, an urban planning study requires more special tools.
A. Approaches	Ask the class to comment on two different schemes for a large city traffic study: a *cordon* system and a *screen-line* system.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. *Cordon* system	Sketch a grid system of streets on the chalkboard. Show outer and inner *cordons* of O & D stations, one around the city limits and the other around the downtown area.
2. *Screen-line* system	Now sketch a number of *screen-lines* through the city. State that an analysis would be almost impossible for either system. Explain that even by ignoring the complete tie-up of traffic that would result from either the downtown cordon or the downtown screen-lines, the O & D patterns are too complicated to analyze. Show by a few desire lines the "spider web" that would result from the many criss-crossing traffic movements in a city.
3. *Land use*	Tell the class that the basic principle in urban transportation planning is to relate travel to *land use*. To obtain discussion on this concept, ask the class why this relationship is used. Explain that with large concentrations of people and large traffic generators (such as factories, office buildings, and shopping centers) it has been found that travel can be related mathematically to land use. This relationship holds because unusual individual trips tend to average out when large amounts of traffic are involved.
B. Techniques in the land-use system	Tell the students that trips are related to land-use by measuring the types of trips and the types of land-use and then correlating them. For example, trips are made for work, school, shopping, and social-recreational uses. Land use in a business district is categorized as retail

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	service, office, wholesale, etc.
1. Trip generation	Explain that internal urban trips are determined from home-interview surveys or similar surveys. These give the pattern of travel by time of day, purpose of trip, income group, and other characteristics. Further explain that an external cordon is usually established to get the external traffic into or through a city. Point out that this lesson is a *brief* introduction only and much has been omitted, such as truck-taxi surveys, and bus routes.
2. Trip distribution	Tell the class that the first step in analysis is to find the number of trips per unit of land for each type of land use. The next step is to distribute the trips among the zones which make up the area. Remind the class that what they previously learned of the different mathematical models is used in the distributing of trips among zones.
3. Traffic assignment	Explain that the trips are assigned by computer to the existing street network. Any new facilities needed to relieve congestion are then determined. Point out that this procedure makes allowance for future trips (based on prediction of future land use). Also adjustments are made for trip generation factors. These adjustments are made to account for increased car usage, income group, etc.
C. The plan	Mention that the complex urban planning differs in several respects from the simpler rural planning. Explain the need to consider other modes of travel and alternative land uses.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	Tell the class that several dozen plans may be considered in an urban study. Each of these plans is compared by computer to each of the other plans in the traffic assignment program. This is done to get the most satisfactory total transportation plan for all modes of travel.
	Explain to the students that the selection of new routes in urban planning is more subjective than in rural planning. It is more strongly influenced by considerations of socio-economic values, boundaries of school and voting districts, and other elements.
	State that computers are used to analyze and process mountains of data but that professional judgment is still required, as in any other engineering work.
IV. Brief Course Review	Remind the class that the 15 lessons in this course have given them only the beginning of a knowledge of the DOT processes.
	Tell the students that in all their future work they must remember that the mission of the Department is to provide transportation facilities that will give the best and safest service for the least cost.
	Read the titles of Lessons 2-15, and give a brief description of each: 2. Need for a new road and the best location 3. Highway systems and responsible agencies 4. Road inventory and field scoring 5. The correct mapping tool for the job 6. Traffic volumes and destinations 7. Analysis and movement of traffic 8. Predicting future traffic 9. The cheaper and better route

VEO #14.0302
DOT #206.388

TRAINING COURSE FOR

FILE CLERKS

The material in this guide is presented in the form of suggestions. Every student participating in this program will be different in regard to education, experience, and ability. The instructor must, therefore, adjust and adapt the suggestions in this guide to the needs of individual students.

The first step in insuring this adjustment is to secure as much information as possible about each new student. This can be accomplished through study of the pre-enrollment information gathered by the Center counselors. The second step is to keep up to date on the progress of each student through the regular use of the information prepared by Individual Program Control (IPC). With this information on hand the instructor can effectively adapt specific objectives, teaching methods, and time alloted to each aspect of the training, directly to the student's needs.

This guide will aid the instructor in accomplishing part of his job. It will provide performance objectives, suggest time allotments, unit outlines, and supplemental teaching aids. Only the instructor, however, can combine these factors with a knowledge of each individual student.

Course Objectives:

The file clerk program at Gila River Career Center is designed to:

1. develop in the student an awareness of the importance of office work and of the career opportunities which it offers.

2. develop an understanding of the place and purpose of the office in general and the file clerk in particular in the typical business organization.

3. develop a job-centered approach to businesslike work habits and attitudes and effective human relations.

4. prepare the student to perform the fundamental tasks commonly required of all beginning office workers.

5. prepare the student to perform the technical tasks commonly expected of the file clerk.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	10. Designing the features for service 11. Establishing the line and grade for service and economy 12. Safety for lives and property 13. Laws and authority to permit highway development 14. Sources of funding and funding problems 15. Complex highways require special tools
V. Summary	Tell the students that if they are especially interested in any topic in the course they will profit from reading more than the assigned references. Offer the students the full reading list and encourage them to develop the habit of reading more fully in technical highway literature. Point out that modern society demands that professional people be articulate in speech and fluent in writing. Remind the class that in professional work they must be able to prove to others that they have sound professional judgment. The principles learned in this course are applicable to many situations. Ask for comments on the scope and content of the course.

QUESTIONS FOR REVIEW

1. Why is it necessary to use computers for transportation planning studies in urban areas?

2. What general mathematical models are most commonly used in these studies?

3. What is the basic principle underlying today's urban transportation planning?

TEACHING HINTS FOR THE INSTRUCTOR

Elements of Highway Planning is one of a series of units (or courses) which provide fundamental information to prepare your students for advanced work. Follow the content as closely as possible. Keep in mind that topics other than those in this unit are covered in other units of the Highway Technicians Program. The units are planned to be given in numerical order.

Plan each lesson before you present it to your class. You will need to plan classwork, discussion, and review. The left-hand column of each lesson contains suggested topics to be covered. The right-hand column gives accepted techniques, methods, and tips, as well as related information which should help you achieve effective teaching. You should review each lesson before class and arrange for needed visual aids and reference material.

Use the chalkboard, overhead projector, charts, diagrams, and other visual aids to clarify the material being presented. Duplicate for student use any important reference material. Give typical job situations as illustrations whenever possible.

Give a summary of key points at the end of each lesson. Also refer to past and future lessons and remind the students of needed references and other materials for the next lesson. Emphasize to the students that answers to the questions for each lesson provide a good summary of the important points.

As you use this course guide, you may have ideas for improving its content. Address any suggestions you wish to make to the New York State Education Department, Bureau of Continuing Education Curriculum Development, Albany, New York 12224.

ABSTRACT - Developed by the New York Department of Education and the State Department of Public Works, this teacher's guide is for instructor use in teaching soils and drainage information to help relieve the shortage of highway technicians. The highway technician program is intended to help provide additional technicians and engineers by training personnel employed in lower-level technician jobs. The contents of this document, illustrated with line drawings, include 11 lessons, among which are: (1) soil and rock deposits in New York State, (2) soil description, classification, explorations, and water, (3) engineering properties of soils, and (4) highway drainage. Each lesson, designed for 2 hours and 40 minutes, contains cited references, objectives, a content outline, an assignment, and some contain questions for review. A glossary of symbols, a three part final examination, and a bibliography are included. Related documents are available as VT 013 359, VT 013 360, and VT 013 062 (all in this issue). (GEB)

4. How is trip generation determined?

5. How is trip distribution performed?

6. How is traffic assigned?

7. How many alternative plans are commonly evaluated in an urban study?

ASSIGNMENT

1. Read pages 3-15, 407-430, and 471-484 in Ref. A.

2. Read Chapter 4 in Ref. F.

3. Read the following articles in Ref. N: "Land Use and Transportation," April 1965; "Composite Networks--A New Planning and Testing Tool," January 1966; "Planning Transportation Facilities To Guide Urban Development," April 1966.

4. Read Ref. S.

5. Read Ref. Y.

6. Read Ref. Z. Write 100-200 words giving your opinion of the model concept versus the old-fashioned *judgment concept* for developing an urban transportation plan.

FOREWORD

This Teacher's Guide, Soils and Drainage, is intended to be used primarily to improve the skills and technical knowledge of certain members of the team which plans, constructs, and maintains highways.

The New York State Department of Public Works, recognizing the shortage of highway technicians, called upon the State Education Department for assistance in developing inservice training to overcome the shortage.

John L. DeLee, who is now Principal Civil Engineer in the Bureau of Highway Planning of the Department of Public Works, initiated and carried on the planning of the curriculum, aided by other personnel from the District Offices of that Department. Mr. DeLee also acted as liaison with the Bureau of Occupational Extension and Industrial Services of the State Education Department. Edward Umiker, Associate Civil Engineer in the Buffalo District Office, and Ralph Fimmano, Senior Civil Engineer in the Utica District Office, collaborated in developing topical outlines for the nine Units (or courses) in the Highway Technicians Program--five of which are now published, four yet to come.

This Guide, Unit V, was written by Lyndon H. Moore, Associate Soils Engineer in the Bureau of Soil Mechanics of the DPW, under the guidance of Berton P. Plummer, Associate in the Bureau of Occupational Extension and Industrial Services. E. Noah Gould, Associate in the Bureau of Continuing Education Curriculum Development, supervised the review and final preparation of the manuscript for publication.

To all the agencies and individuals mentioned above, this Bureau makes grateful acknowledgment for the responsibilities they so faithfully fulfilled. For permission to reproduce illustrations, thanks are also due to the New York State College of Agriculture at Cornell University for Figures 2-1 and 2-2; the National Research Council for Figures 8-7 and 8-8; and Armco Steel Corporation for Figures 7-7, 11-1(a), 11-1(b), 11-1(c), and 11-1(d).

PREFACE

The rapid expansion of the state and federal highway building program has caused a serious shortage of qualified technicians and engineers for planning, supervision of construction, and maintenance of highways. The New York State Department of Public Works, recognizing this shortage, called upon the State Education Department to assist in planning an educational program to overcome this shortage.

These two departments together planned to develop the additional technicians and engineers by training personnel employed in the lower-level technician jobs. This Teacher's Guide and the others in the Highway Technicians Program are a product of that planning. They are published as aids to the teachers of the upgrading classes.

Local boards of education and other sponsors of adult education programs are being encouraged to offer Soils and Drainage and the other courses in this Program as part of vocational-industrial education. Besides drawing students from the Department of Public Works in the job categories mentioned above, students will also be drawn from the public works departments of counties, cities, and towns; in addition, technicians, estimators, and junior engineers employed by construction contractors will be found in these classes.

The units of the Highway Technicians Program--this being Unit V, and the latest published--have been planned for sequential offering. Sufficient subject matter has been suggested in each lesson for about 2 hours and 40 minutes of classroom instruction. The total length of the course may be adjusted to fit in with the prior experience and education of enrollees.

Units so far published in the program are:

Unit I.	Basic Mathematics Review	1961
Unit II.	Highway Drawing	1961
Unit III.	Highway Surveying	1962
Unit IV.	Preliminary Highway Planning	1962
Unit V.	Soils and Drainage	1967

Units contemplated for future publication are:

Unit VI. Highway Design and Estimating
Unit VII. Highway Construction and Inspection
Unit VIII. Highway Structures
Unit IX. Highway Maintenance

General Occupational Education II

Robert S. Seckendorf
Assistant Commissioner for
Occupational Education

Course Outline:

The following table provides a listing of course units along with time estimates for each unit. Both sequence and estimates can be varied to meet student needs. Units are presented concurently as students achieve objectives that prepare them to move ahead.

Course Unit	Title	Hours	Code
Unit I	Occupational Orientation	5- 7	-01
Unit II	Fundamentals of Typing	70- 85	-02
Unit III	Office Equipment	10- 15	-03
Unit IV	Communications	15- 20	-04
Unit V	Financial Activities	8- 10	-08
Unit VI	Record Management	30- 40	-09
Unit VII	Sources of Information	3- 5	-05
	Total	141-182	

TO THE INSTRUCTOR

Soils and Drainage is the fifth in a series of nine courses which provide fundamental information to prepare your students for advanced work in highway planning, design, construction, and maintenance. Follow the content as closely as possible. Keep in mind that topics other than those in this unit are covered in other units of the Highway Technician Program. The units are planned to be given in numerical order as adult (or continuing) education courses.

In general, lessons in each of the units are to be given in a session of two hours and 40 minutes. You may adjust this period to fit the class level, time schedule, and classroom situation.

Lesson Format

Plan each lesson before you present it to your class. You will need to plan classwork, discussion, and review. The lefthand column of each lesson contains suggested topics to be covered. The righthand column gives accepted techniques, methods, and tips, as well as related information which should help you achieve effective teaching. Specific pages for assignments are given in each lesson. You should preview each lesson and arrange for needed visual aids and reference material.

Give a summary of key points at the end of each lesson. Also refer to past and future lessons, and remind the students of needed references and other materials.

Many of the illustrations in the text can be reproduced and distributed to the class to aid in teaching and for the future reference of the students. You can get a set of master copies for duplicating by writing to:

Director, Bureau of Soil Mechanics
New York State Department of Public Works
1220 Washington Avenue
Albany, New York 12226
Attention: Training Coordinator

The Soils Engineer in each of the State's DPW District Offices can supply you with copies of forms for gradation tests, compaction tests, drill logs, and any other reference data published by the Bureau of Soil Mechanics. You can also get soil samples for the lesson on visual identification and sieves for the lesson on soil classification from the District Soils Engineer. If he cannot supply you with any of the materials mentioned, contact the Director of the Bureau of Soil Mechanics.

A set of about 40 slides (35 mm.) has been prepared, showing many actual examples of the soils problems discussed in the course. You can get these slides on loan from the Director of the Bureau of Soil Mechanics. It is suggested that you show them after the students have covered Lesson 10.

This course contains 11 lessons. For some of the lessons you may need more than the standard session of two hours and 40 minutes. The presentation of the whole course may require up to 15 sessions. Lessons 6 and 8 are particularly long and may require two sessions each.

Selected References

A list of 13 references is given in the bibliography. The references used in each lesson are also shown on the first page of the lesson. The basic text for the course is Ref. A, B. K. Hough, Basic Soils Engineering, and you should encourage the students to buy their own copies. The book may be obtained from a book store or from

The Ronald Press Company
15 East 26th Street
New York, New York 10010.

The price of this book is $9.50 as of March 1966. A discount of 20 percent is allowed on orders of 25 or more copies. Also, the instructor may be able to obtain a free desk copy on request.

The Highway Research Board publications should be available in the library of all DPW District offices. Free copies of the drainage handbooks (Refs. L and M) may be obtained for the class by sending a request to Armco and Bethlehem Steel companies.

Examination

A final examination is provided at the end of this Guide. The questions are in the form of multiple choice, true-false, and matching questions. The correct answers given in each case, needless to say, are for the instructor only, and the spaces are to be left blank in presenting the questions to the students.

Comments Solicited

As an instructor uses this course guide, he may have ideas for improving its content. Any suggestions he wishes to make should be addressed to The New York State Education Department, Bureau of Continuing Education Curriculum Development, Albany, New York 12224.

Lesson 1 - Introduction to the Course

REFERENCE CITED IN THIS LESSON

Hough, B. K. Basic soils engineering. New York. The Ronald Press Co. 1957. (Referred to in this unit by symbol "A")

OBJECTIVES

1. To get acquainted with class members
2. To provide a general description of the course
3. To explain the value of each phase in the training of a technician
4. To describe the basic types of soil materials and bedrock

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Introduction	* Print the name of the course and your name on the chalkboard. Give the students a brief description of your experience.
II. Purpose of Course	* Explain that the course is given to improve the knowledge of technicians in soils and drainage and to help them advance in their jobs in highway design, construction, and maintenance. * Add that material in this course will be valuable for future Department of Public Works examinations for the engineering titles.
III. Introduction of Class Members	* Have each student introduce himself to the class, volunteering information about himself, such as name, occupation, and where employed.
IV. Required Student Equipment	
A. Textbook	* Write the name of the basic textbook for the course, Ref. A., on the chalkboard. * State that it would be advisable for each student to have his own textbook since it can be used as a reference book for many years.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	soils engineer, but to give him the basic soils knowledge he will need in his future engineering career.
VII. Course Description	* Explain that 90 percent of the course will be concerned with soils, the remainder with drainage.
A. Title and brief resume of each lesson	* Explain briefly the subject material which will be covered in each of the 11 lessons of this Unit.
1. Introduction to the course	* Lesson 1 will be concerned with the study of the importance of soils engineering in highway construction and design.
2. Rock and soil deposits of New York State	* Lesson 2 will deal with the history of the deposition and formation of the rock and soils of New York State. Recognition of various types of soil deposits from land forms will be covered. This study will help to show how the soils and rock can vary on a typical highway project.
3. Index properties of soils	* In Lesson 3 the basic tests for measuring the index properties of soils will be presented. These tests are used in highway engineering to compare various soils and to predict their behavior as construction materials.
4. Soil description and classification	* In Lesson 4 the basic method used by New York State Department of Public Works for visual identification of soils will be presented, using soil samples. Some of the soils classification systems used outside of New York State will also be discussed.
5. Soil explorations	* Lesson 5 will be concerned with the methods of conducting a soil survey for a highway project. Indirect exploration methods involving geologic reports, pedology (agricultural soil maps), airphoto interpretation, and seismic investigations will be explained. Direct exploration methods, which involve making a hole in the ground by

22307

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	various techniques, will be covered in detail. Drilling equipment should be available for class inspection and instruction.
6. Engineering properties of soils: consolidation and strength	* Lesson 6 will be primarily concerned with the engineering properties of soils. When soil is used as an embankment or as a structure foundation, it must have enough strength to support the load. Also, the amount of consolidation or settlement of the foundation soil should not adversely affect the riding qualities of the pavement. Laboratory tests and methods for analyzing settlement will be discussed. Design solutions commonly used for highway stability and settlement problems will be reviewed.
7. Soil water	* Lesson 7 will deal with the types and behavior of soil water and the influence of each type on the design, construction, and performance of highways.
8. Compaction of embankment soils	* Lesson 8 will deal with earthwork inspection as performed in the field. Discussion of the mechanics of compaction, the standard compaction test, and field inspection will be included.
9. Compaction control test, granular subbase courses, and stabilized soils	* Lesson 9 will cover a detailed description of the field compaction control test as conducted by earthwork inspectors. The purpose, use, and requirements of granular subbase courses under pavements, and the types of stabilized soils used for highway shoulders will also be discussed.
10. Influence of soil conditions in construction and design problems	* Lesson 10 will involve an analysis of earthwork design and construction problems. The soils knowledge gained in the previous sessions should help the student understand the problems and solutions.
11. Highway drainage	* Lesson 11 will cover the types of highway drainage problems. It will

22308

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Ask students to sign a sheet of paper so that a group order may be made.
	* State that the course varies somewhat from the textbook. In the course, the soils theory is presented as concisely as possible, and emphasis is placed on demonstration of soil principles by examples of soil behavior in highway construction.
B. Looseleaf notebook	* Suggest that students keep a looseleaf notebook for course notes. The instructor may consider mimeographing sheets listing the content outline to facilitate note-taking. The course notes will be valuable for future reference.
V. Course Prerequisites	* State that the students must have some knowledge of basic mathematics, since no time will be spent in reviewing the subject. The mathematics needed includes: 1. Basic trigonometry and geometry 2. The content of Basic Mathematics, Unit I of this series
VI. Purpose of Course	* Summarize this introduction by explaining the aims of the course: 1. To develop an appreciation of the different types of soil deposits 2. To become acquainted with the details of testing necessary for construction supervision 3. To understand some of the principles that determine soil behavior 4. To develop an ability to recognize, understand, and solve the soil problems that are commonly encountered in highway design and construction * Mention that the intent of this course is not to make the student a

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	include application of the principles of hydrology to predict the frequency and intensity of runoff, and the principles of hydraulics to design drainage facilities.
12. Final examination	* At the end of the Unit is a final exam, with questions on problems a highway technician will encounter.
VIII. Importance of Soils in Highway Construction	
A. Economics	* The basic assignment of a highway engineer is to construct an adequate highway system by the most economical methods. Thus, the importance of the following:
1. Cheapest construction material	* For highway construction soil is the most common and cheapest building material available. Ninety percent of the volume of materials in a highway is earth.
2. Importance of knowledge of soils	* Explain that an understanding of the engineering properties of soils is essential for the most economic use of soils in design and construction.
3. Earthwork share of total highway costs	* State that earthwork accounts for 31 percent of all the money spent on highway construction. Large economic savings can be realized by the efficient use of soils in highway design and construction. Distribute copies of Figure 1-1 and discuss it.
B. Basic uses of soils	* Mention that in highway construction soils are used for the following purposes (Fig. 1-2): 1. In its original position, as a foundation to support embankments and structures, and to provide cut slopes 2. As a material for embankment construction 3. As a support for pavements in cuts and fills

FIGURE 1-1
DISTRIBUTION OF HIGHWAY CONSTRUCTION COSTS
1965

UNIT I (14.0302-01)

OCCUPATIONAL ORIENTATION

Performance Objectives:

Upon completion of this unit the student will be able to describe orally the general purpose and organization of business. She will be able, as determined by instructor observation, to demonstrate good interpersonal relations with other class members and good organization of a work station.

The student will be able to demonstrate in a role playing, or other simulated situation, the proper dress and grooming for an office worker and correct techniques and good manners. She will be able to score 80% on an objective test covering the responsibilities of a receptionist.

Unit Outline:

A. Review of Modern Business Enterprise

1. Methods of organization
2. Purposes of business

B. Types of Offices and Opportunities for Office Workers

C. What Business Expects of Office Workers

1. General expectations
2. Appropriate attire
3. Posture and figure control
4. Complection and health
5. Personal hygiene

D. Office Techniques of Etiquette

1. Basic good manners
2. Application of social graces to office situations
3. Some special problems that occur

E. Interpersonal Relations

1. Role of motive and emotion
2. The office worker's role in business-human relations activities

2200

CONTENT OUTLINE TEACHING POINTS AND TECHNIQUES

Embankment Section

Cut Section

① Foundation to support embankments, cut slopes and structures
② Embankment material
③ Support for pavements

FIGURE 1-2
USES OF SOILS IN HIGHWAY ENGINEERING

C. Basic requirements of soils as construction material

* Explain that to be used in these ways soil must meet the following requirements:

1. It must have enough strength to support the applied loads of embankments, structures, and traffic under all climatic conditions without shear failure.
2. It must be able to support the above loads without undergoing objectionable deformation or settlement.

D. Treatment of soils

* Mention that the soils may need treatment during construction to improve their strength and settlement properties for satisfactory performance as foundation and embankment material. Knowledge of this treatment is important in highway engineering.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
IX. Comparison of Soils to Other Construction Materials	* Explain that analysis of soil is even more complex than the analysis of construction materials like concrete and steel. (Ref. A, Chap. 1)
A. Properties of steel and concrete	* State that steel and concrete are relatively uniform solids which have predictable strength properties within the elastic range of loading.
1. Control of strength	* The strength may be "ordered" in the manufacture of steel and in the making of a concrete mix. This strength will be constant under all climatic conditions. Structures can then be built of these materials with confidence in their strength.
B. Properties of soils	* Explain that soils are composed of a mixture of three dissimilar materials: soil, water, and air. The properties will be influenced by the action of each of these materials in the soil mass.
1. Factors influencing strength	* Some of the factors influencing the strength of soil are: 1. Size, shape, and distribution of soil particles 2. Degree of packing of soil particles 3. Amount of water in soil 4. Climatic variations
C. Understanding the properties of soils	* Emphasize that it is important to understand the fundamental properties of soils to use them as construction material. The fundamentals are not the same as for steel and concrete.
X. The Growth of Soils Engineering	* Soils engineering is a phase or subdivision of structural engineering. It deals with soils as foundation materials upon which structures rest and with soils as structural materials. * From information previously covered some of the important differences between conventional structural engineering

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	and soils engineering are apparent.
A. History	* Man's earliest attempts at construction probably involved soil. As civilization developed through many centuries, man learned by trial and error about soil as foundation material.
1. Recent and current	* Since World War I much greater understanding of the behavior of soil has been achieved by applying the principles of physics, mechanics, hydraulics, strength of materials, and structural engineering. This approach to analyzing soils problems is called "soil mechanics."
B. Limitations of theoretical approach	* Because soil is very complex an entirely theoretical solution of most soil problems is not practical.
C. Practical approach to soils problems	* The most practical solution to soil problems can be reached by a combination of the following sources of information:
1. Experience	* Experience was obtained by trial and error in the past; this developed into the empirical or "rule of thumb" procedures of today. The weakness of this type of experience is that it does not recognize differences in the engineering properties of soils. What works well at one location may not succeed with the type of soil at another location.
2. Laboratory testing	* Information on the properties of soils can be obtained by field explorations and laboratory tests.
3. Scientific principles	* Scientific principles from various fields of engineering and science are used to explain or predict the behavior of soils under various conditions.
XI. Basic Types of Soil Material	
A. Definition of soil	* Define soil as sediment and unconsolidated mineral material which have

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

been produced by physical disintegration and chemical decomposition of rocks. It includes the total amounts of air, water, organic material, and other substances that may be mixed with the mineral material.

B. Classification of particle size

* Point out that the most useful method of classifying soils is by particle size. Natural soil deposits usually contain mixtures of these materials. Soils may be classified as follows:

SOIL	UPPER SIZE LIMIT	LOWER SIZE LIMIT
Boulders	None	12 inches
Cobbles	12 inches	4 inches
Gravel	4 inches	1/10 inch
Sand	1/10 inch	3/1000 inch
Silt	3/1000 inch	1/12,000 inch
Clay	1/12,000 inch	None

1. Class demonstration

* Show the class samples of various soil sizes so they can retain mental pictures of them. Mention that soils are measured by the smallest dimension. Natural soils are usually mixtures of two or more soil sizes.

2. Identification of silt and clay

* Indicate that particles from boulder size to sand can be identified by eye. Silt and clay particles, however, are too small to be distinguished by eye.

* Silt and clay can be identified by their behavior under various conditions.

a. Silt

* Silt may be considered finely ground-up particles with about the same grain size as powdered sugar. It is non-plastic; water will appear on the surface of a moist silt sample when shaken in the hand.

b. Clay

* Clay consists of extremely fine, plate-like particles which cannot be seen under an ordinary microscope. Each particle has an electric charge

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	which attracts a film of water to its surface. This condition gives clay putty-like properties and makes it plastic. Plasticity is the main difference between silt and clay.
XII. Basic Types of Rock	* Explain that an understanding of the basic types of bedrock is important since rock cuts are often involved in highways. Also, all of the soils are derived from bedrock.
A. Igneous rock	* State that igneous rock is formed by molten masses of rock pushed up from deep below the surface of the earth and hardened by cooling.
1. Types	* Variations in type of igneous rock result from their mineral content and rate of cooling. The best known igneous rocks are granites, gabbro (traprock), and volcanic lava. The igneous rock found in New York State is usually very hard.
B. Sedimentary rock	* Emphasize that sedimentary rock is the most common type. It is found over three-quarters of the earth's surface. It is formed from gravel, sand, silt, and clay particles deposited in layers at the bottom of former lakes, seas, and rivers. Some types of sedimentary rock contain organic remains of marine life and chemical precipitates formed in water.
1. Types	* The principal types of sedimentary rock are as follows:
a. Sandstone	* Sandstone consists of grains of sand cemented together. It was formed as beach and delta deposits and often shows ripple marks. Sandstone may be very hard.
b. Shale	* Shale was formed from clay hardened by pressure into rock. It was usually formed in the deep, quiet water of ancient lakes or seas. Shale is often

22215

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	thin-bedded or layered and breaks up into thin slabs. It is used in the manufacture of brick and cement.
c. Limestone	* Limestone was formed from deposits of the remains of sea life (such as coral, worms, algae, and shells) and from precipitation of calcium carbonate. Limestone varies in color and appearance. It is used in the manufacture of cement and as a principal source of coarse aggregate in New York State.
d. Conglomerate	* Conglomerate is composed of rounded pebbles cemented into a mixture of finer material. It was formed by beach action and by action at the mouths of swift rivers.
e. Mixtures	* Sedimentary rocks often appear as mixtures, such as a sandy shale or a shaley limestone. Shaley limestone is an important source of cement.
f. Layers	* In New York State sedimentary rock often consists of layers ranging in thickness from several inches to several feet. These deposits may consist of various combinations of shale, limestone, and sandstone.
C. Metamorphic rock	* State that metamorphic rock is formed from sedimentary or igneous rock that has undergone tremendous pressure or heat or both. The result is a change in the structure of the rock. "Metamorphic" is a combination of the Latin words for change and form.
1. Types	* The principal types of metamorphic rock are as follows:
a. Slate	* Slate is formed from shale. It is harder than shale and often shiny in appearance.
b. Marble	* Marble is recrystallized limestone. It is often tinted with varied colors.

CONTENT OUTLINE	TEACHING POINTS AND TECNHIQUES
c. Quartzite	* Quartzite is altered sandstone. It is usually extremely hard and difficult to drill.
d. Schist	* Schist is highly changed rock with crystals oriented in wavy parallel planes. Mica is often found in this rock.
e. Gneiss (pronounced "nice")	* Gneiss is highly changed rock with crystals appearing in thin bands.
XIII. Fossils	* Touch on the subject of fossils by stating that they are the remains, prints, or other indications of former plant or animal life found buried in rock. Studies indicate that the older the rocks the simpler the types of plant and animal fossils found in them. The fossils have been used to establish the age of the rock which encloses them.

QUESTIONS FOR REVIEW

1. Review the high points of the lesson.
2. Remind the students to bring notebooks for use at next session.
3. Emphasize the need for regular attendance and punctuality.

ASSIGNMENT

1. Read Chapter I of Ref. A.

Lesson 2 - Soil and Rock Deposits of New York State

REFERENCES CITED IN THIS LESSON

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill Book Co. 1960. (Referred to in this unit by symbol "B")

OBJECTIVE

To describe the history, characteristics, and surface land-form appearance of the major rock and soil deposits in New York State and their significance in highway engineering

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Physiographic Regions of New York State	* Define physiography as the description and classification of land forms. The major physiographic regions of the State are shown in Figure 2-1. Distribute Figure 2-1 to class. (Ref. C, pp. 56-59)
A. Engineering significance of physiographic regions	* Mention that major changes in topography define the boundaries of these regions. * State that each region has individual features for land relief, type and structure of bedrock, and type and characteristics of soils. * The engineering problems involved with highway design and construction will vary from one region to another.

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

FIGURE 2-1
PHYSIOGRAPHIC AREAS OF NEW YORK STATE
(Source: Ref. D, p. 6)

B. Description of regions

* Mention that there are seven lowland and five highland regions in the State. The lowland areas occupy about one-third of the total area and contain the majority of the population and major transportation systems.

* The rock and soil characteristics will be developed in further detail in the following sections.

II. Rock Geology of New York State

* Mention that this section on the early geologic history of the State is presented for general background. It is not necessary for the student to remember the sequence of events in detail.

A. Introduction

* For hundreds of millions of years every square inch of the earth's surface has been subjected to tremendous opposing forces of construction and destruction.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Uplift forces	* The forces of uplift, originating deep in the interior of the planet, periodically force the crust of the earth to buckle and bend upward, creating mountain ranges and plateaus.
2. Destructive forces	* In opposition, the forces of the atmosphere in the form of water, wind, and glaciers constantly strive to erase the earth's high places and transport their materials to the valleys and the sea.
3. Time element	* During the span of a lifetime the progress of these forces is barely perceptible.
B. History of the rock deposits of New York State	* Mention that the age of the world is estimated to be between two and five billion years. * Pass out the bedrock map of New York (Fig. 2-2) to be used with the following section.
1. Adirondack Mountains 500,000,000 years ago	* Point out that the oldest rock in New York is in the Adirondack Mountains, where a huge shield of molten igneous rock was pushed up about 500,000,000 years ago. * This igneous rock, which is mostly granite, was pushed through an even older deposit of sedimentary rock that was changed by heat and pressure into marble, quartzite, and gneiss. Patches of these metamorphic rocks are found throughout the Adirondacks. * The original mountains were much higher and have been cut down by erosion.
2. Age of shallow seas 500,000,000 to 200,000,000 years ago	* For 300,000,000 years most of New York was covered by a vast, shallow sea, which extended over much of the North American Continent. * A land mass existed in the Atlantic Ocean with its western boundary near the present New England Coast.

F. Personal Attributes

1. Punctuality

2. Physical health

3. Integrity

4. Leadership

5. Attitudes

G. Personal Efficiency in Identifying Responsibility, Planning and Organizing Work and Work Stations.

Supplemental Teaching Aids:

Excellent resource people for this unit are working secretaries, State Department of Public Instruction personnel, beauty school operators or department store buyers and nurses.

The best general resource book is the Arizona State Department of Vocational Education's Suggested Curriculum Guide in Vocational Office Procedures. A good resource for role playing is Case Problems: for Vocational Office Block Project. This is available from the Department of Vocational Education also. Other useful resource books are: You as a Secretary, Royal Typewriter Company. How to be a Super Secretary, Remington Rand, and Sheaffer's Handbook for Secretaries, W. A. Sheaffer Pen Co., Fort Madison, Iowa ($1).

Some very good films are applicable to this unit. For example: "Office Etiquette" (15 min.), Britannica Press, Chicago, Ill., "Office Teamwork" (12 min.), Britannica Press, and "Off to a Beautiful Start", Scott Paper Co., Philadelphia, Pa.

Training Time 5-7 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	the rate of ice melting, and the ice front remained stationary. The plastic flow of the bottom ice continued in these periods. The lower ice carried large amounts of debris which was piled up at the foot of the glacier.
1. Moraine	* Moraine is the term used for the ridges of soil built up around the glacier at a temporary stopping point. The surface of the moraine is usually irregular with depressions and hummocky hills. The material consists of unconsolidated till. (Distribute Figures 2-3 and 2-4 to the class.)

Formation of Terminal Moraine

Glacial Stream Deposits

FIGURE 2-3
FEATURES OF GLACIATION

22326

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Relation of till to bedrock	* Have the class refer to the bedrock map of New York (Fig. 2-2). Mention that the composition of the till is determined by the type of bedrock immediately to the north of the deposit. The stones are usually, but not always, angular and sharp-edged. (Ref. D, pp. 10-11)
a. Limestone and shale areas	* In limestone and shale areas the till is predominantly clay and silt.
b. Sandstone areas	* In sandstone areas the till is sandy.
c. Granite rock areas	* In the areas of the Adirondacks and Westchester County, where granite bedrock exists, the till consists of boulders, gravel, sand, and silt.
3. Condition of till	* Till is usually very compact, but the surface five feet may be loose from weathering and frost action.
4. Thick till	* State that thick till has a wavy and hummocky ground surface. Bedrock is deep and does not influence the surface topography.
5. Thin till	* In areas of thin till, such as on hillsides, the topography is influenced by the underlying bedrock. It is important to classify till in two categories as highway cuts often encounter bedrock in thin-till areas.
6. Drumlin	* A drumlin is an elongated, streamlined, cigar-shaped hill composed of till that has been overridden and shaped by the glacial ice. The long axis of the hill parallels the ice movement. These hills are 50 to 150 feet high and are common in the Erie-Ontario Plains Province.
B. Ice contact deposits	* Explain that after many years the climate warmed up and the glacier began to recede to the north. During this recession there were periods when the rate of ice advance was equaled by

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* In the quiet waters of the glacial lakes the finer-sized silt and clay particles were deposited.
1. Bottom sediments	* State that bottom sediments containing clay have limited strength and present foundation problems for constructing embankments.
a. Varves	* A combination of a silt layer and a clay layer is called a varve. Usually glacial lake sediment was laid down in consecutive layers of light-colored silt and darker-colored clay. Each layer may be 1/32- to 1/2-inch thick. The clay layers were laid down in winter when little sediment was carried into the lake, and the silt layers were laid down in the summer when there was more turbulence and more sediment entering the lake.
b. Surface features	* The topography is level to hummocky with gully development by present-day streams.
2. Delta deposits	* Explain that where the glacial streams entered lakes the velocity of the water decreased suddenly. The coarser materials were dropped from suspension and deposited in a fan-shaped formation at the mouth of the stream.
a. Surface features	* Deltas have smooth tops and steep sides around their borders. They may consist of layered silt, sand, and gravel. The coarser materials are usually on top, and the size of particles decreases with depth.
b. Beaches and bars	* At the boundaries of the glacial lakes, beaches and sand bars were formed. They consist of assorted sand and gravel with a predominance of sand. These deposits are common in the Erie-Ontario Plains Province as the Great Lakes were at a higher elevation than today.

22329

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* The bars, the elongated ridgelike land forms, and the beaches appear as smooth, slightly sloping areas. They offer sources of granular material for highway construction in areas where other sources of gravel are scarce.
E. Marine bottom sediments	* Mention that the crust of the earth was elastically depressed by the tremendous weight of ice. When the ice sheet receded to Canada an arm of the Atlantic Ocean extended into the St. Lawrence and Champlain Valleys. These areas were covered with marine, or salt-water, silt and clay. The crust of the earth rebounded slowly, and the sea water receded over thousands of years.
1. Clay properties	* Clay deposited in salt water is brittle in structure and sometimes offers more serious embankment foundation problems than fresh-water clay.
V. Postglacial Deposits	* Define postglacial deposits as soils that have been formed or laid down since the time of glaciation.
A. Alluvial	* State that materials deposited by modern streams are termed alluvial. These materials are usually in a loose condition. The type of material deposited depends on the velocity of the stream. Alluvial deposits usually consist of silt and sand, but may include gravel and cobbles.
1. Surface appearance	* Alluvial soils represent smooth, flat areas adjacent to present-day streams. In broad valleys they may be thought of as flood-plain deposits. When a stream meanders across a valley, attention should be given to old stream channels, filled with organic soil, which may present foundation problems. These channels may be covered up with later flood-plain deposits.

22330

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Mountain building in New England 350,000,000 years ago	* About 350,000,000 years ago there was a tremendous mountain range pushed up along the Atlantic Coast.
	* The mountains of New England and the Highlands-of-the-Hudson in southern New York are remnants of this mountain range.
a. Rock in the Hudson Valley	* The pressures of upheaval changed the sedimentary rocks along the eastern New York State border to slates and schists.
	* The upheaval folded the sedimentary rocks in the Hudson Valley.
b. Rock in the Catskill Mountains and Southwestern Plateau	* The exposed, nearly horizontal layers of sandstone and shale in the Catskill Mountains and the Southwestern Plateau were formed from sediment eroded from this new land mass.
4. Formation of the Appalachian Mountains 170,000,000 years ago	* About 170,000,000 years ago the Appalachian Mountains were formed to the south of New York State.
a. End of seas in New York State	* At that time the whole area of New York State was raised never to be covered by a sea again.
b. Formation of Palisades	* A later period of volcanic activity produced the basalt sheet that forms the Palisades along the lower part of the Hudson River.
c. Subsequent erosion	* For millions of years up to the time of glaciation, starting a million years ago, erosion took place over New York State, and the major stream valleys existing today were formed.
5. Rock deposits in local areas	* Discuss the characteristics of the rock deposits in the local area of the class, and relate these to the geologic sequence described above.

22322

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
III. Glacial History of New York State	* Mention that it is important to understand the effect of glaciation on the landscape of New York State, as most of the present-day soil deposits resulted from an ice sheet covering the State. This section on glacial history is intended as background information in preparation for the topic of glacial deposits.
A. Formation of a glacier	* Explain that glaciers form when snow accumulates faster than it melts off, over a long period of time.
	* As the accumulating snow thickens it changes to ice. When the ice becomes 100 to 200 feet thick the bottom layers become plastic from the pressure of the overlying ice.
	* The plastic bottom ice moves toward the edges of the glacier, causing the whole mass to move.
B. Continental glaciers	* In the past climatic conditions have been favorable for formation of continental glaciers that covered large areas of North America, Europe, and Asia.
	* These glaciers were similar in appearance to those in Greenland and the Antarctic today.
1. Volume of former glaciers	* Present-day glaciers cover about 10 percent of the surface area of the world. During the last period of glaciation ice covered about 30 percent of the surface area of the world. It is estimated that the volume of frozen water in the glaciers at that time was enough to lower the water level in all the seas and oceans by 300 feet.
2. Thickness of ice	* The ice was thousands of feet thick. The maximum measured thickness of the existing Greenland glacier is 10,000 feet near the center.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
C. Glacial period in New York State	* Explain that, at a time estimated to be a million years ago, there was a change in climate causing the formation of huge glaciers or ice sheets in Labrador and the Hudson Bay region of Canada. The glaciers advanced and receded across the northern United States several times during this glacial period.
1. Thickness	* The last ice sheet expanded southward covering all of New York State, except a very small area in Cattaraugus County, with several thousand feet of ice. The ice covered the highest peaks of the Adirondack Mountains.
2. Southern boundary	* The southern boundary of this ice mass extended from Cape Cod on the east, across Long Island, through Pennsylvania, along the Ohio River, and through Illinois, Iowa, and Minnesota to Canada.
3. Ice retreat	* The ice disappeared from New York State about 10,000 years ago.
IV. Glacial Deposits of New York State	* Mention that the combination of the tremendous weight of ice and the fluid-plastic movement of the lower ice planed down the mountains and widened and deepened the existing valleys. (Ref. C, pp. 59-61)
A. Glacial till	* State that tremendous amounts of rock and soil were ground up, mixed together, carried short distances to the south with the ice movement, and then laid down in a very compact condition under the ice. These deposits are called glacial till and consist of variable mixtures of stones, gravel, silt, and clay. In extreme cases till may be 99 percent clay or 99 percent stones.
1. Occurrence and surface appearance	* Glacial till is the most common soil deposit found in New York State and covers three-fourths of its land area.

22324

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Terminal moraine	* Terminal moraine refers to the moraine formed at the end of the glacial advance. The northern half of Long Island is a terminal moraine. Here the hummocky moraine hills are several hundred feet high.
C. Glacial stream deposits	* Indicate that, as the climate warmed, the stagnant ice melted rapidly. Water from melting ice flowed off the top and through ice tunnels or canyons. The water flowed southward into the valleys, depositing large amounts of soil.
1. Kames	* Water flowing down through holes in the ice left conical hills of roughly sorted sand, gravel, and silt, called kames. Water flowing in the notch between the ice and the valley walls left series of irregular kames, sometimes called kame terraces, on the edge of the valleys. (Fig. 2-4)

FUNDAMENTALS OF TYPING

Performance Objectives:

Upon completion of this unit the student will be able to type at a rate of 30 wpm/ecol.

Unit Outline:

A. Machine Fundamentals

1. Parts

2. Maintenance procedures

3. Manual and electric typewriters

4. Operation

B. Quality and Performance Standards

1. Speed and accuracy

2. Neatness

3. Language arts

C. Skill Development

1. Keyboard mastery

2. Manipulation of machine parts

3. Speed, accuracy and erasing

D. Typing Applications

Supplemental Teaching Aids:

No suggestions will be made for this unit since free or inexpensive resources are not applicable.

Training Time 70-85 hours

TEACHING POINTS AND TECHNIQUES

* Eskers were formed by material deposited in streams flowing through or under the ice. They are long, winding, narrow, steep-sided ridges and are almost triangular in cross-section. They consist of sand, silt, gravel, and cobbles,and sometimes provide a source of granular construction materials. (Fig. 2-4)

* The rivers flowing from the melting glacier carried all sizes of soil particles. The larger cobbles, gravel, and sand sizes were dropped from suspension in order of size as the stream velocity decreased. Outwash deposits consist of stratified rounded cobbles, gravel, and sand. Outwash is the best source of gravel for highway construction.

es * The identifying land form is a smooth and pitted plain that gradually slopes down valley. Frequently outwash deposits occur as terraces above the present valley bottom. (Fig. 2-4)

* Occasionally, deep, steep-sided depressions are found in an outwash plain. These depressions were formed when blocks of ice were detached from the receding glacier. The ice was covered with sand and gravel, and, when it melted, a depression was formed. These depressions are often filled with organic deposits and present foundation problems for highway embankments. Other kettle holes appear as lakes.

* Throughout the State many temporary lakes were formed in the valleys. In south-flowing valleys temporary dams were formed by moraine deposits or blocks of ice. In north-flowing valleys the dams were formed by the ice sheet. Tremendous quantities of water from melting ice supplied these lakes.

22328

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

FIGURE 2-2
IMPORTANT BEDROCK AREAS OF NEW YORK
(Source: Ref. D, p. 10)

a. Deposition of sediments	* Sediment washed in from this land mass formed deposits of sedimentary rock thousands of feet thick across most of New York. The continent was depressed slowly under the weight of the accumulating material, enabling a great thickness of sediment to be deposited in shallow water.
b. Variations in sedimentary rock	* The variations in strata of shale, limestone, and sandstone we find today resulted from changes in climate, water depth, and the type of material deposited during this great period of time. The sediment was consolidated into rock under the influence of pressure and time. * The deep salt deposits of western New York were formed from evaporation of salt water in very shallow seas over long periods of time.

22321

MICROCOPY RESOLUTIO
NATIONAL BUREAU OF STA

N TEST CHART
ANDARDS-1963-A

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
5. Mixtures	* All of the organic deposits described above may occur as mixtures of different soils, or mixtures with various amounts of sand, silt, and clay.
6. Meadow	* Meadow is a poorly drained area which may contain organic deposits. Investigation is required.
C. Manmade fill	* State that in urban areas manmade fill of assorted materials may be found. This type of fill should be examined thoroughly since it is usually placed over the most undesirable land and often covers organic deposits.
D. Residual soil	* "Residual" describes soil developed from weathering of the bedrock in place. In parts of the world that were not glaciated, much of the soil was formed in this manner, but in New York State there is very little residual soil.
VI. Summary of Soil Deposits	* Summarize previous sections on soil deposits by discussing Figure 2-4.
A. Area concept of soils	* State that all soil deposits can be classified into these groupings. All the soil in a given deposit should have the same engineering properties since it consists of material deposited by the same geologic process. The boundaries of a deposit may be determined by the characteristic land form.
B. Application of the area concept to a highway project	* On a highway project the land forms in an area can be determined by field reconnaissance and by studying air photos, agricultural soil maps, and exploration data.
1. Use of exploration data	* The information obtained from exploration may be used to estimate the engineering properties of the entire deposit. This reduces the number of explorations required.

22332

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Highway design	* Knowledge of the land forms and of the engineering properties of the soils will enable the designer to determine the most economical location for alignment and grade, to evaluate design problems for each type of soil deposit, and to determine sources of granular borrow.
3. Highway construction	* The type and extent of soils to be encountered during construction may be predetermined, and construction problems may be anticipated before they occur.
C. Usefulness of the area concept	* The usefulness of the area concept cannot be fully appreciated in this early part of the course. It will be demonstrated in the following lessons.
VII. Description of Local Area	* Discuss the major soil deposits in the local area where the class is being held. (Ref. D, Soil Map)

ASSIGNMENT

1. Review notes and become familiar with definitions presented in this lesson.

22333

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Class problems	* Work out several problems in class, starting with simple problems involving one relationship. More complicated problems involving several relationships may be attempted after the class is familiar with the basic definitions.
Problem 1	* The weight of a container of moist soil is 152 grams. After drying in an oven, the dry soil and container weigh 131 grams. The container weighs 45 grams. What is the moisture content of the soil? Answer: 36 percent
Problem 2	a. A sample of soil weighs 106 pounds and its volume is 0.86 cubic feet. What is the wet density of the sample? Answer: 123.5 pounds per cu. ft. b. If the moisture content is 22 percent, what is the dry unit weight? Answer: 101.0 pounds per cu. ft.
Problem 3	a. A 40-pound sample of dry sand just fills a container of 1/3 cubic foot volume. If the specific gravity is 2.70, what is the void ratio? Solution: $G = \frac{\gamma_s}{\gamma_w} = \frac{W_s}{V_s \gamma_w}$ $V_s = \frac{W_s}{G\gamma_w} = \frac{40}{(2.70)(62.4)} = .235$ cu. ft. $V_v = V - V_s = .330 - .235 = .095$ cu. ft. $e = \frac{V_v}{V_s} = \frac{.095}{.235} = .405$ Answer: e = 0.41

22341

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	b. If the above sample were saturated with water, what would be the moisture content? Solution: $W_w = V_v \gamma_w = (.095)\ (62.4) = 5.93$ $w = \frac{5.93}{40} = .15$ Answer: w = 15 percent
Problem 4	* The moisture content of a sample is 20 percent. The void ratio is 0.7 and the specific gravity is 2.70. What is the degree of saturation? Answer: S = 77 percent
Problem 5	* A large stone, whose volume was computed to be 1 cubic foot, weighed 165 pounds. What is the specific gravity of the stone? $G = \frac{\gamma_s}{\gamma_w} = \frac{\frac{W_s}{V_s}}{\gamma_w} = \frac{\frac{165}{1}}{62.4} = 2.65$ Answer: G = 2.65
IV. Soil Consistency	* The physical properties of clay soils differ greatly at different moisture contents. A clay sample may vary from a liquid condition, to a plastic condition, to a bricklike condition, depending on the moisture content. The term used to describe the condition of a clay soil is "consistency," expressed in such terms as soft, firm, or hard. (Ref. A, p. 43)
A. Mechanics of consistency	* The state in which a clay soil exists depends on the amount of water in the soil.
1. Liquid state	* In the liquid state the clay has an excess of water between soil particles. As the water content is reduced, the clay particles come closer together, and the sample becomes plastic.

22342

Lesson 3 - Index Properties of Soils

REFERENCES CITED IN THIS LESSON

Hough, B. K. Basic soils engineering. New York. The Ronald Press Co. 1957. (Referred to in this unit by symbol "A")

Lambe, T. W. Soil testing for engineers. New York. John Wiley and Sons, Inc. 1951. (Referred to in this unit by symbol "F")

New York State, Department of Public Works, Bureau of Soil Mechanics. Albany, New York. Visual identification of soils. The Bureau. Undated. (Referred to in this unit by symbol "E")

OBJECTIVES

1. To define and explain the significance of soil index properties
2. To describe the tests for determining soil index properties
3. To explain the use of these index properties in construction and design

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Introduction	* State that the basic problem in building a highway is determining how the various soils will behave as foundation and embankment material. Certain simple tests will indicate the index properties and the suitability of a soil for a given use. Many of these tests are conducted in the field as part of construction control.
II. Soil Gradation by Particle Size	* Explain that the size of soil particles and the distribution of sizes throughout a soil mass are important factors which influence soil properties and performance. (Ref. A, Chap. 2)
A. Method of testing	* The size and distribution of soil particles are determined by a sieve analysis.
1. Demonstration	* Use a nest of sieves for demonstration.

22334

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Explain the numbering system of sieves: e.g. "No. 40 sieve" indicates 40 openings per inch.
	* A sieve full of dry soil is shaken thoroughly. The soil then remaining on the sieve is weighed.
	* Work out a simple problem, listing in tabular form on the chalkboard for each sieve size: the weight retained, the percentage retained, and the percentage of total sample passed.
	* Explain the importance of washing the sample through the No. 200 sieve.
	* Silt and clay particles will bind together or adhere to fine sand, and this gives erroneous results for the percentage retained on No. 200 sieve if the sample is not washed through. This is very important in field tests as the No. 200 sieve is the critical grain size for some specifications.
B. Grain size distribution	* There are several systems for classifying soil according to grain size. We will use the system adopted for use in New York State. (Ref. E)
	* Explain that, for convenience, sieve sizes are used as soil size limits.
C. Method of presentation	* The standard procedure for presenting gradation analysis is to plot percent finer by weight versus grain size. It is suggested that form SM37A1, which is available from the Bureau of Soil Mechanics, be passed out to the class and a typical problem be worked through from a set of sieve results. (Visual aid: Show soil sample being sieved.)
1. Typical test presentation	* Indicate: 1. How to determine the percent finer from weight retained on a sieve

22335

UNIT III (14.0302-03)

OFFICE EQUIPMENT

Performance Objectives:

Upon completion of this unit the student will be able to score 90% or above on an instructor established scale that considers both accuracy and time, in operation of adding machines and calculators.

Unit Outline:

A. Ten-key Adding Machines and Printing Calculators

1. Adding by touch
2. Subtraction
3. Multiplication
4. Decimals and fractions, conversions
5. Division on printing calculators

Supplementary Teaching Aids:

No resource book suggestions are provided due to the nature of this unit. As a general overview of business machines the following film might be considered; "Modern Business Machines", Teaching Aids Exchange, 307 South B Street, San Mateo, Calif. 94401.

Training Time 10-15 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	2. How to determine the percentages of gravel, sand, and silt from the graph at bottom of test form 3. Grain size, plotted on a logarithmic scale because of the large range in particle sizes (Largest particle is a million times the smallest.)
D. Significance of curves	* The shape of a gradation curve is an important indicator of the engineering properties of a soil. 1. Show on the chalkboard Figure 2-5 from page 18 of Ref. A. 2. Discuss well-graded, skip-graded, and uniform soils, and how engineering properties vary. (Ref. A, p. 19) 3. The gradation test is conducted as a control on gravel items used for highway construction. This test is made in the field project soil laboratories.
E. Hydrometer test	* The No. 200 sieve is the smallest practical size for sieve analysis. For determining the grade of a finer particle size, the hydrometer test is used. The features of the test are as follows: 1. The soil is dispersed in water in a glass cylinder about 18 inches high. 2. The velocity at which the particles fall out of suspension is measured. (The largest particles drop fastest.) 3. A hydrometer similar in shape to those used for testing automobile batteries is placed in the solution. The specific gravity of the solution, which decreases as the soil settles out of solution, registers on the hydrometer.

22336

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

headings: term, symbol, definition, and units as shown in the handout sheet labeled Figure 3-1.

FIGURE 3-1
SOIL WEIGHT AND VOLUME RELATIONS

C. Unit weight or density (γ)

* Explain that unit weight or density is an important indication of the effects of compaction of soil. (Ref. A, p. 27)

1. Wet unit weight (γ_t)

W = total weight of sample

V = total volume of sample

* Wet unit weight is defined as weight of soil and water per unit volume, and is measured in pounds per cubic foot. In symbolic terms:

$$\gamma_t = \frac{W}{V}$$

2. Dry unit weight (γ_d)

W_s = weight of soil

* Dry unit weight is defined as weight of soil per unit volume, and is also measured in pounds per cubic foot.

$$\gamma_d = \frac{W_s}{V}$$

3. Typical values for wet unit weight

* The wet unit weight of natural soils in place varies widely. (Ref. A, pp. 30-31)

22338

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	4. By use of conversion charts, the amount and size of soil solids remaining in suspension can be determined from the readings. Repeated readings at established time intervals make it possible to determine the proportion of each grain size in the soil sample.
	5. The hydrometer test is not conducted in field project laboratories.
III. Physical Measurements	* The physical measurements of the weight and volume properties provide simple tests to estimate the strength and compressibility properties of a soil sample. These measurements can also be used to determine the similarity of various soil samples. It is important to understand these tests, as some of them are used in the field for embankment compaction control, which will be studied in a later lesson.
A. Basic parts of a soil sample	* Every soil sample consists of three parts (Fig. 3-1): 1. Soil particles 2. Soil water in the void spaces between soil particles 3. Air in the void spaces between soil particles
B. Weight and volume nomenclature and relationships	* To simplify the mental picture of the volumes and weights of the component parts of a soil sample, assume that in a cylinder the solids, water, and air can be separated and shown diagrammatically. (Fig. 3-1)
V = total volume of soil mass V_V = volume of voids (nonsoils) V_S = volume of soil solids	1. Explain letters and subscript labels. 2. Use Figure 3-1 to explain the definitions that follow under content outline, C through G. 3. As terms are defined, list them in a table with the following

22337

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
F. Void ratio (e)	* The void ratio is defined as the ratio between the volume of voids and the volume of solids. $e = \frac{V_v}{V_s}$ (no units) 1. For sands the void ratio varies between 0.40 for a dense sand and 1.0 for a loose sand. 2. For clays the void ratio varies between 0.50 and 2.0. 3. The void ratio is an indication of the strength and compressibility of a soil.
G. Degree of saturation (S)	* The degree of saturation is defined as the ratio of the volume of water to the volume of voids in a soil sample. $S = \frac{V_w}{V_v}$ expressed as a percent S = 100 percent for a saturated sample * S is used as decimal when working weight-volume problems.
H. Relationship of definitions	* Refer the student to Figure 3-1 and a chart of definitions which will be made available to him, for working out sample problems. (Handout Fig. 3-1)
1. Useful relations	* From the basic definitions, it is possible to work out the following relation: $Gw = Se$ * This is too involved to work out in class. Present this, without deriving it, as a useful equation to solve problems. * Another useful relation is as follows: $\gamma_d = \frac{\gamma_w}{1 + w}$

22340

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Organic deposits	* Organic deposits were formed when the remains of organic plant life were deposited under water. The lack of oxygen in the water nearly stopped the decomposition process. This has permitted deposits to build up to depths of more than 50 feet in the thousands of years since the glacier receded. Organic deposits present critical foundation problems for embankments because of their high compressibility and low strength.
1. Peat	* Peat contains partially decomposed but still recognizable plant fibers. Its fibrous structure contains over 90 percent water by volume. The color ranges from brown to black.
2. Muck	* Muck is organic material more completely decomposed than peat; plant fibers are no longer visible in it. Its color is black.
3. Organic silt and organic clay	* Organic silt and organic clay are swamp deposits which contain the remains of microscopic organisms.. The organic material, which cannot ordinarily be seen by the naked eye, gives the soil a fluffy structure. Occasionally shells and organic fibers can be seen in it. These soils have the appearance of soft silt or clay, dark gray in color, and are weak and compressible. They are commonly found in western Long Island and the tidewater areas of the lower Hudson River.
4. Marl	* Marl is a calcium deposit which is soft and has the color and consistency of toothpaste. It is formed by precipitation in water from the remains of animal and plant life containing calcium carbonate. It is found in limestone bedrock areas where the ground water contains calcium carbonate, and usually underlies muck.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Plastic state	* Plasticity is defined as the ability of a soil to undergo deformation without rupture. It may be thought of as "putty-like" property.
3. Semisolid state	* Further drying causes the continuous water films to break, and air enters the voids. This is the semisolid state. Because the clay particles are extremely small (submicroscopic in size), the water molecules next to the clay particles are held by a strong molecular attraction.
4. Shrinkage forces	* These layers of water exert increasing shrinkage forces on the sample, hold the dry soil tightly together, and give it a bricklike consistency. Tensile forces of a large magnitude are created at the boundaries between the water and air, pulling the soil together. This is called capillarity, and will be discussed later.
5. Solid state	* When a clay soil reaches its minimum volume after shrinkage, it passes into a solid state. (Fig. 3-2)
B. Importance of consistency	* The strength of a clay soil will vary greatly with the amount of water in the sample. Seasonal variations in moisture become important in clay soil.
C. Atterberg limits and indices	* About 50 years ago, an agricultural scientist named Atterberg devised a series of tests to determine the moisture content at which a clay sample passes from one state to another. * Refer to Figure 3-2, and define the Atterberg classification system. Show samples of clay in liquid, plastic, and semisolid states.
1. Liquid limit (LL)	* The liquid limit (LL) is the moisture content at which a remolded clay soil starts to exhibit shear strength.
a. Test procedure	* Describe the mechanics of the test. (Ref. F, p. 24) Demonstrate equipment, if available.

22343

FIGURE 3-2
SHRINKAGE OF CLAY SOIL
WITH DECREASE IN MOISTURE CONTENT

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Plastic limit (PL)	* The plastic limit (PL) is the lowest moisture content at which the soil can be rolled into a thread 1/8 inch in diameter without breaking.
a. Test procedure	* Describe the mechanics of the test. (Ref. F, p. 25) Demonstrate the test.
b. Plastic limit and compaction	* Clay may be best compacted when the moisture content is at or slightly below the plastic limit. Farmers find clay soil most tillable at the plastic limit.
c. Color change	* The color of the clay becomes lighter at the plastic limit since air begins to enter the voids.
3. Shrinkage limit (SL)	* The shrinkage limit (SL) is defined as the moisture content required to fill the voids when the sample reaches its minimum volume. This limit is not widely used, and only a definition is required.
4. Plasticity index (PI)	* The plasticity index (PI) is the numerical difference between the liquid and plastic limits. 1. Present a numerical example. 2. The plastic index indicates the spread of moisture content over which the soil will exhibit plasticity.
5. Shrinkage index	* Define the shrinkage index as the numerical difference between the plastic limit and shrinkage limit. * There is little engineering significance to the shrinkage index.
6. Atterberg limits applied to New York State soils	* Remember that Atterberg limits are moisture contents representing consistency boundaries for remolded soils.
a. Average limits for New York State	* Plastic clay: LL = 40 percent PL = 20 percent PI = 20 percent

22345

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Silt with a trace of clay: LL = 25 percent PL = 15 percent
	* Slightly plastic: PI = 10 percent
	* Silt, sand, and gravel with small amount of clay: LL = 20 percent PL = 15 percent PI = 5 percent
	* Neither silt, sand, nor gravel without clay is plastic.
b. Trend of limits	* As the proportion of either silt, sand, or gravel (or any mixture of them) increases, the LL and the PI decrease. The PL decreases more slowly.
7. Use of Atterberg limits	* Atterberg limits are used: 1. To compare plasticity characteristics of different soils 2. To estimate the suitability of soil for embankment construction 3. To estimate the suitability of granular soils containing small amounts of clay for uses such as subbase course gravel 4. To estimate compressibility and strength of foundation soils

ASSIGNMENT

1. Study index properties in Chapter 2 of Ref. A.

22346

UNIT IV (14.0302-04)

COMMUNICATIONS

Performance Objectives:

Upon completion of this unit the student will be able to demonstrate to the satisfaction of the instructor, a level of coherence and clarity in oral communications that is adequate for the business office. The student will be able to prepare and write a mailable letter or brief report, from facts provided by the instructor. In a role playing, or other simulated situation, the student will be able to demonstrate correct telephone technique, procedure, and usage. The student will be able to score at least 80% on an objective test covering mail handling and telegraph procedures and use.

Unit Outline:

A. Oral and Written Communications

1. Importance of oral and written communications

2. Importance of good listening

B. Elements of Good Speech

1. Voice control

2. Vocabulary and pronunciation

3. Grammar

C. Speech and Writing Problems

1. Individual analysis

2. Corrective activities

D. Review of Rules for Punctuation, Capitalization, etc.

E. Importance of the Voice in Telephone Usage

1. Control

2. Enunciation

3. Resonance

4. Tone

5. Distance between lip and mouthpiece

2204

Lesson 4 - Soil Description and Classification

REFERENCES CITED IN THIS LESSON

Hough, B.K. Basic soils engineering. New York. The Ronald Press Co. 1957. (Referred to in this unit by symbol "A")

New York State, Department of Public Works, Bureau of Soil Mechanics. Albany, New York. Visual identification of soils. The Bureau. Undated. (Referred to in this unit by symbol "E")

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill Book Co. 1960. (Referred to in this unit by symbol "B")

OBJECTIVES

1. To learn the technique of describing soil by a visual inspection of the material

2. To become acquainted with the soil classification systems in general use

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Introduction	
A. Soil description	* Soil description is necessary for predicting the engineering properties and behavior of a soil.
1. Purpose	* Explain that soil description conveys a definite meaning to people who have not had the benefit of examining the soils at firsthand and who desire to estimate the engineering properties of the soil.
2. Simplicity	* Soil description must be simple, as it is often made in the field without the aid of any special equipment.
3. Use	* State that soil description of exploration samples makes it possible to determine depth and boundaries of various types of soil deposits.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
4. Need for practice	* Point out that it is not always easy to prepare a good soil description because of the variable character of the material. Practice is required.
B. Soil classification	* State that soil classification consists of conducting one or more index property tests on a sample to place a soil in a certain class.
1. Purpose	* The purpose is to estimate the engineering behavior of the soil according to its class and to compare one soil with another.
2. Index properties	* Explain that the index property tests used, which were studied in the previous lesson, are: moisture content, gradation, Atterberg limits, density, and specific gravity.
II. Soil Description	* Soil description consists of systematic observation and tabulation of the following items (A through E under Content Outline):
A. Description of grain sizes	* State that this involves the determination of the proportion of each component of the soil by grain size.
1. System used by NYSDPW	* For consistency, one system of description should be used in an organization. The New York State Department of Public Works uses the system described on page 1 of Ref. E.
2. Grain size limits	* Review grain size table; suggest converting millimeter scale to inches.
3. Proportions	* Show how proportions are described by adjective system.
B. Grain size	
1. Description of coarse-grain soils	* State that coarse-grain particles of soil are those that can be seen by eye. They are all sizes coarser than the No. 200 sieve opening.

22348

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
a. Estimating proportion	* Spread out sample and estimate proportion of total sample by weight of cobbles, gravel, and sand. Since specific gravity values of all samples are about the same, the proportional volume of each material is the same as its proportion by weight. Drying the sample will help separate the particles in it.
2. Description of fine-grain soils	* State that particles of fine-grain soil cannot be seen by eye. These are silt and clay sizes smaller than No. 200 sieve opening.
a. Difficulty of grain size estimate	* It is obvious that a visual description of grain size is impractical when the grains cannot be seen.
b. Description by behavior	* Fine-grain soils must be described by their behavior. The main difference between a clay and a silt is plasticity. The .002 mm. boundary between silt and clay is not considered practical. Eliminate it from the chart on page 1 of Ref. E.
c. Silt and clay identification	* Field observations to identify silt and clay are listed on page 3 of Ref. E, and in Section 8, pages 32-33 of Ref. B. Discuss and demonstrate before the class. * A practical method of distinguishing between silt and clay is to cut a moist sample with a knife or wire. If the surface of the cut is shiny, clay predominates; if the surface is dull, silt predominates.
d. Dry soils	* Some fine-grain soils will be hard and dry in nature and will have to be moistened to make the preceding field observations.
3. Description of mixtures	* Mention that mixtures of the two major soil groups, i.e. granular and fine-grain soils, are more difficult to describe.

22349

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Drying the sample may simplify separating silt.
	* Estimate plasticity of fines.
	* Samples with more than 60 percent granular material will feel like granular material when rolled in a ball between the hands.
	* Samples with more than 40 percent fine-grain soil will feel like fine-grain soil when rolled between hands.
	* Most glacial till soils are mixtures of coarse- and fine-grain soils.
C. Class participation	* Emphasize the importance of grain-size description and the need for practice by the class to become proficient. Designers and field men should become familiar with the description system by identifying samples. This will enable them to have a mental picture of soil described on exploration logs in future projects.
	* Samples of soils in each grain-size class should be examined, by eye and hand, by each individual.
	* Samples of typical soils found in the general geographical area of the class should be available. Class members should prepare a visual grain-size description of each sample. Set up a columnar form on the chalkboard to be filled in. Allow enough space to put in additional description to be discussed in the next section.
	* Discuss the characteristics of samples as related to geological deposit and land form as presented in Lesson 2.
D. Other important characteristics for soil description	* Explain that grain-size description is not sufficient to fully describe a soil. Other items are very important, (Ref. E, p. 2; Ref. B, Section 8, p. 34), such as:

22350

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Color	1. Color
2. Moisture	2. Moisture condition (by adjective description) a. Soils from below the water table are always wet.
3. Shape of particles	3. Shape of coarse-grain soil particles a. Angular--sharp edges; usually found in glacial till b. Rounded--caused by transportation in water; found in water-laid deposits, sometimes in till c. Flat--usually shale
4. Consistency	4. Consistency a. Coarse-grain soils--loose or compact b. Fine-grain soils--plastic or nonplastic; soft, medium firm, hard, or stiff
5. Gradation	5. Overall gradation a. Well-graded b. Skip-graded c. Uniform--soil particles are all the same size
6. Other features	6. Other features of the sample--varves, fissures, shells, fibers, etc.
E. Organic soils	* Show the organic soil samples to the class and mention that pure organic soils are not difficult to describe. When organic soils are mixed with mineral soils the description becomes more difficult. The colors are dark, and the soil usually has an organic odor. * The kinds of organic soils are:

22351

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	1. Peat--fibrous, black to brown
	2. Muck--no structure or fibers, black
	3. Organic silt--dark gray with occasional shells or organic specks; feels light and fluffy
	4. Marl--consistency of toothpaste, white to gray, often mixed with mineral soils and shells
III. Soil Classification	* Explain that a soil classification system consists of a systematic arrangement of classes of soils based upon the relationships among their physical properties.
	* Coarse-grain soils are classified by grain-size distribution.
	* Fine-grain soils are classified by plasticity (Atterberg Limits).
	* The class of a soil may be estimated by a visual description and can be checked by laboratory tests.
A. Classification systems	* Indicate that there are two well-known classification systems in use today. It is not necessary for the students to know the details of each system but only the general arrangement.
1. Unified system	* Mention that the unified system is used by the U. S. Army Corps of Engineers and the U. S. Bureau of Reclamation. (Ref. B, Section 8, pp. 28-29; or Ref. A, p. 482)
	* Describe the letter abbreviations and the 15 soil groups.
2. AASHO system	* State that this system was introduced by the U. S. Bureau of Public Roads to classify soils by their performance as subgrade soils under pavements. (Ref. B, Section 8, p. 24)

22352

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Now describe the eight major soil groups.
	* Mention that classification is based on a series of charts using various relations from the results of grain-size gradation and plasticity tests combined.
3. Use in NYSDPW	* Explain that the requirements for gravel items used in construction by the State Department of Public Works are based on classification tests.
	* For example, granular subbase material must meet gradation and plasticity test standards as stated in specifications.
	* State that a classification system is not used for routine soil descriptions.
	* Classification tests are used in problems involving analyses for embankment stability, cut stability, and structure foundations.

ASSIGNMENT

1. Review Ref. E.

22353

Lesson 5 - Soil Explorations

REFERENCES CITED IN THIS LESSON

Hough, B.K. Basic soils engineering. New York. The Ronald Press Co. 1957. (Referred to in this unit by symbol "A")

Woods, K.B. Highway engineering handbook. New York. McGraw-Hill Book Co. 1960. (Referred to in this unit by symbol "B")

OBJECTIVE

To explain the methods for obtaining the information about rock and soil that may influence the design, construction, and performance of a highway system.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Types of Exploration	* Mention that there are two general types of exploration available.
A. Indirect methods	* Enumerate the indirect methods employed in obtaining information: from the fields of geology, pedology (study of soils for agricultural purposes), airphoto interpretation, and geophysics (seismic investigations).
B. Direct methods	* State that direct methods involve putting a hole in the ground by the use of drill rigs, power and hand augers, probe rods, and test pits.
II. Engineering Problems	* Explain that the purpose of an exploration is to provide information to solve the engineering problems concerned with design and construction.
III. Progression of a Soil Survey	* Point out that soil explorations should progress during all the design stages of a highway project.
A. Reconnaissance survey	* Mention that at the start of a highway project a general appraisal should be made of the typical soils that will be encountered. The concept

22354

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	of geological deposits and land forms discussed in Lesson 2 is applied. 1. The indirect methods of exploration should be used. 2. If some areas appear to be critical, field explorations are used. 3. Line changes may be made at this stage to avoid areas of critical soils that will be expensive to stabilize in order to support embankments and/or structures.
B. Preliminary survey	* Explain that preliminary survey is made during development of preliminary plans: 1. Borings are made at structure locations. 2. Foundations for high embankments are investigated. 3. Cut locations are explored to determine type of material. 4. Survey is made for availability of construction materials.
C. Detailed survey	* Set forth that in many areas preliminary explorations are sufficient to solve engineering problems or to indicate there are no problems. In areas of critical problems, such as swamp crossings, detailed explorations will be required.
IV. Exploration Tools--Indirect Methods	* Explain that the importance of each tool varies with the type of problem. Often several tools are used to obtain the answers.
A. Geology	* State that geology is defined as the study of the composition and arrangement of rocks and soils.
1. Published geologic reports	* Mention that there are geologic reports published by the State Museum which give detailed geology of most areas of New York State.

22355

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Pedology	* Define pedology as the study of surface soils (upper 3 feet) for agricultural purposes.
1. Principles of pedology	* Explain that when like soils are subject to identical conditions of climate, topography, and time, they will develop identical soil profiles.
2. Soil profile	* State that in pedology the soil profile used extends down to the parent soil, which is unaltered by weathering. It is usually at a depth of 2 to 3 feet, but may be 6 feet.
a. A horizon	* Explain that the surface layer, usually 12 inches thick, is the zone of topsoil and leaching. Percolating water and chemical action have removed finer material from this layer.
b. B horizon	* Explain that the zone of deposition is at an average depth of 1 to 2 feet. The finer material from above is deposited in this layer. In some areas of New York State, this layer is cemented and very impervious.
c. C horizon	* Explain that this layer consists of the unaltered parent soil.
3. Soil series	* State that the most important class of identification is the soil series. This series classifies soils derived from the same parent material and having similar characteristics
a. Nomenclature	* Soil series are given names taken from the place names near the spot where they were first defined, such as Chenango, Lordstown, Ontario, and Farmington.
4. Agricultural soil maps	* Inform the class that the United States Department of Agriculture has published agricultural soil maps for most of New York State.

22356

F. The Telephone Directory

1. Alphabetical directory

2. Classified directory

3. Out-of-town directory

G. Types of Telephone Services

H. Handling Calls

1. Incoming calls

2. Outgoing calls

I. Types of Telegraph Services

J. Preparation of Messages

1. Choice of class of service

2. Use of special words and code

3. Cost of transmission

4. Time differences (zones)

K. Importance of Mail

L. Procedures of Handling Mail

M. Classification of Mail and Rates

N. Postage Equipment and Supplies

1. Postage meters and scales

2. Automatic addressing systems

Supplemental Teaching Aids:

Many good resource books applicable to this unit are available, particularly in the field of special education. Others are the following: Communicating Facts and Ideas in Business, Leland Brown, Prentice-Hall, Englewood Cliffs, N.J., 1961, Business English in Communications, Himstreet, Porter and Maxwell, Prentice-Hall, Englewood Cliffs, N.J., 1964.

A series of three programmed texts by Joseph C. Blumenthal are available from Harcourt, Brace, and World. A great deal of free material is available from Western Union including the film "Telegram for America". Pitney-Bowes, Inc. distributes two publications on mailing machines entitled How to Increase the Prestige of Your Mail and 29 Timely Mailing Tips.

Training Time 15-20 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
a. Map information	* These maps indicate boundaries of various soil series, descriptions of parent material, and the type of deposit: glacial till, outwash, lake-laid clay, etc.
5. Use of agricultural soil maps	* Mention that these maps are valuable in a preliminary reconnaissance to determine the location, boundaries, and types of soil deposits that will be encountered.
a. Discussion of soil map for local areas	* Show the class a soil map of a local area and discuss features and principal soil series shown. Relate this with glacial deposits discussed in Lesson 2. Maps can be borrowed from District Soils Engineer.
(1) Limitation	* Remind the class that the principal limitation of a soil map is that it does not give sufficient information about the soil to the depth encountered in highway work.
b. Airphoto interpretation	* Explain that stereoscopic examination of aerial photos is sometimes used to determine the types and limits of soil deposits.
(1) Factors in identification	* For additional details on factors, see Section 10, page 38, of Ref. B. 1. Land forms 2. Drainage and erosion 3. Soil tones 4. Vegetation 5. Land use
c. Engineering soil maps - New York State Department of Public Works	* State that for major highway projects on new locations, engineering soil maps are prepared by the New York State Department of Public Works.
(1) Information	* The soil map shows the boundaries of each soil type. The soils are grouped into 16 depositional groups based on the type of glacial or post-glacial deposit. (Fig. 5-1)

22357

CONTENT OUTLINE TEACHING POINTS AND TECHNIQUES

GEOLOGIC AGE	GEOLOGIC ORIGIN	DEPOSITIONAL UNIT
GLACIAL	ICE DEPOSIT	Thick Till
		Thin Till
		Drumlin
		Major Moraine
	STREAM DEPOSIT	Outwash
		Kame Field
		Esker
	LAKE DEPOSIT	Bottom Sediments
		Delta
		Bars & Beaches

POST GLACIAL	STREAM DEPOSIT	Alluvial
	ORGANIC DEPOSIT	Muck & Peat
		Meadow
		Muck Over Marl
	WEATHERED BEDROCK	Residual

FIGURE 5-1
ENGINEERING GROUPING OF NEW YORK STATE SOILS
(For convenience, this chart is repeated from Lesson 2)

(2) Tabular summary

* A tabular summary is included with the map indicating all of the engineering considerations for design and construction problems in each soil deposit.

d. Seismic investigations for highway cuts

* State that the seismic method of subsurface exploration consists of creating sound or vibration waves within the earth by exploding small charges of dynamite 3 or 4 feet beneath the surface. The time of travel of these waves is then measured from their point of origin to each of several detectors, placed at known distances from the source. These sensitive detectors record the amplitude of vibrations and the time it takes for the vibrations to reach the detector.

(1) Wavefront advance

* Explain that the velocity of wavefront advance is a function of the density of the material.

22358

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Velocity of sound waves in rock is two to four times the velocity in soil.
	* The wave will travel down through the soil and then along the surface of rock and generate return waves going up to ground level.
(2) Data recording	* Each detector makes a photographic record of the time it takes for the first wave to arrive.
(3) Determination of rock depth	* Explain that the results of the photographic record are analyzed, and the following information is determined mathematically: 1. The velocity of waves through the overburden, which is a rough indication of the density and type of overburden 2. The velocity of waves through the rock, which indicates the approximate type of rock 3. The depth of rock below the blast location within 5 percent accuracy
(4) Engineering application	* State that seismic explorations are used to determine the depth of the rock and that this information is used for preparation of cross-sections.
(a) Usefulness to designer and contractor	* Point out the uses of seismic explorations: * A steeper cut slope can be used in rock than in earth. Combined slopes are plotted on cross-sections and the right-of-way limits determined. * The rock slopes vary from one-vertical-on-one-horizontal for a very soft rock, to vertical for a sound rock. This information is provided for the designer by geologists.

22359

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* A contractor can estimate more accurately the volume of rock excavation, which results in more realistic bid prices at savings to the State.
(5) Seismic explorations by the NYSDPW	* Relate that the New York State Department of Public Works has two or three seismic crews in the field. The average cost of this work is one-fifth the cost of getting the same information with borings.
V. Exploration Tools--Direct Methods	* The type of exploration used depends on the design information desired. The limitations of the various methods should be recognized, as misleading information is worse than none at all.
A. Soundings or probings	* Define sounding or probing as forcing a rod in the ground and recording the penetration resistance.
1. Methods	* Discuss methods of progressing sounding.
a. Sledge hammer	* The simplest arrangement is to drive a 1-inch diameter, pointed steel rod into the ground with a sledge hammer. Additional 3- to 4-foot sections of rod may be coupled onto the point section.
b. Power-driven hammers	* More elaborate methods use a gasoline or air hammer, or a 25- to 50-pound weight mounted on a small tripod.
2. Limitations	* Explain the limitations of information from sounding.
a. No soil samples	* No samples of the soil penetrated can be obtained. The soil profile is unknown.
b. Cause of refusal indefinite	* Refusal of the tool to penetrate may indicate a boulder, very compact soil, or ledge rock. It is important, in design, to know what caused refusal.

22360

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Useful application	* Explain useful applications of probing. It should be used only by people who know the limitations of the method.
a. Areas of known soil profile	* State that probing is done in areas where borings have determined the soil profile and it is known that soft or loose boulder-free materials are underlaid by compact material.
B. Auger borings	* Define auger borings as explorations progressed by means of rotating a spiral-shaped bit into the ground.
1. Procedure	* State that the auger is advanced a distance equal to its length. The bit is withdrawn, the soil removed, and the procedure repeated.
2. Limitations	* Explain that soil and water conditions determine the major limitations.
a. Water table	* Mention that an auger hole will cave in when the sample is noncohesive sand and gravel below the water table.
b. Soil types	* Point out that augers will not penetrate soil containing cobbles and boulders.
c. Sampling	* Explain that the structure of auger samples is much disturbed. Care is needed to avoid knocking soil from the sides of a hole when inserting the auger.
3. Advantages	* Explain that this is a very economical method of exploration, since it uses light equipment.
a. Water table	* Indicate that relatively shallow water tables can be determined accurately.
4. Hand-auger borings	* Mention that there are two types of hand-augers:

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
a. Post-hole or Iwan digger	* Post-hole or Iwan digger, consisting of a spiral-shaped bucket available in diameters from 3 to 8 inches.
b. Helical auger	* Helical-shaped bit, similar to a carpenter's ship auger, ranging in diameter from 1 to 1-1/2 inches
5. Power auger	* Explain that augers can be rotated, fed, and withdrawn by motor power.
a. Equipment details	* State that power augers are mounted on heavy-duty trucks or crawler tractors. 1. Auger is fastened to a square- or hexagonal-shaft "Kelly bar" which can be rotated and lowered or raised. 2. These units are also used by utility companies for setting poles.
b. Limitations	* State that principal limitations are: 1. Access to site 2. Difficulty in penetrating soil containing boulders
C. Tube sample borings	* Mention that the most common method of exploration utilizes drill holes and tube samples of the soil.
1. Progression of drill hole	* Explain that advancing a drill hole consists of repeating three basic operations:
a. Driving casing	* Driving a length of pipe or casing into the ground by means of a falling weight
b. Cleaning soil out of casing	* Cleaning the soil out of the casing by breaking the soil up with a chopping tool on the end of a hollow drill rod. The soil is washed out of the casing with water under pressure forced out of the end of the chopping tool.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
c. Sampling soil	* Sampling the soil immediately below the bottom of the cleaned casing by forcing downward one of the various types of tube samplers connected to the bottom of a drill rod
2. Drill rig	* Describe the basic parts of the type of drill rig required for soil exploration.
a. Power source	* A gasoline or diesel motor is used as a source of power.
b. Hoisting unit	* Power is transmitted to a cathead hoist through a transmission and clutch assembly.
c. Tripod or derrick	* The tripod or derrick unit has a sheave or pulley on top.
d. Water pump	* The water pump may be driven by the drill-rig power unit or a separate power source.
3. Core drill rig	* Describe the equipment in addition to soil drilling rigs needed to drill rock. For rock drilling, it is necessary to rotate the rock core sampler attached to the drill.
a. Spindle	* The drill rod is attached to a spindle.
b. Power transmission to spindle	* Power for rotation is transmitted to the spindle through the drill head.
c. Vertical movement of spindle	* Explain that a means of raising or lowering the spindle is provided to force the rock core sampler into rock. Three types of units are: 1. A lever arrangement, called a hand feed rig 2. A hydraulic device, called a hydraulic feed rig 3. A mechanical device, called a screw feed rig

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
4. Drive hammers	* State that the falling weight used to drive the sampler is called a drive hammer.
a. Weight	* The two commonest weights are 140 pounds and 300 pounds.
b. Operation	* Explain that the operator lifts the weight by means of a rope running from the drive hammer over the sheave at the top of the tripod and wrapped around the cathead hoist. When the free end of rope is pulled, the friction of the rope on the rotating cathead lifts the drive hammer.
c. Driving energy	* The operator hoists a 140-pound weight 30 inches, or a 300-pound weight 18 inches, and allows the weight to drop on the drill pipe or sampler-spoon drill rod.
d. Recording hammer blows	* The number of hammer blows to drive the casing each foot is recorded. The blows required to drive the sampler every 6 inches are recorded.
5. Soil samplers	* Explain that numerous types of soil and rock samplers are available for various soil conditions.
a. Split-tube drive sampler	* Mention that the split-tube drive sampler is the most widely used and includes a hardened cutting shoe, an 18-inch-long split tube to retain the sample, and a connection for the drill rod. The connection includes a ball check valve that prevents water from draining out of the hollow drill rod and washing out the sample. The structure of samples obtained is disturbed but they are useful for soil description and classification tests.
b. Pressed samplers	* State that these samplers are thin-walled and are intended to be pressed into fine-grain soils to obtain undisturbed soil samples for laboratory testing. The Shelby tube sampler is the most common type.

22364

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
c. Core samplers	* Inform the class that core samplers are used to sample boulders and bedrock. The sampler consists of a cutting bit, a tube to hold the sample, and a connection to the drill rod. Water is circulated to reduce friction. Two types of cutting bits are the tungsten carbide bit and the diamond bit faced with industrial diamonds.
d. Retractable plug sampler	* Explain that a retractable plug sampler is a light portable unit consisting of a tube 1 inch in diameter, with pipe extensions that can be driven into the ground. 1. The lower end has a retractable point which keeps the soil from entering the pipe until sampling depth is reached. 2. The point is retracted inside the tube and a series of 6-inch brass tubes above the open end are filled with soil by driving the sampler. 3. The equipment is useful for sampling soft soils in areas difficult to move a drill rig to.
e. Test pits	* Mention that test pits are holes, pits, or shafts large enough to be accessible to a man, excavated for the purposes of engineering exploration.
VI. Recording Exploration Information	* State the importance of accurately recording all of the information obtained for use in design and construction.
A. Review of drill-hole log form	* Pass out to the class a typical drilling log. Prints of logs may be obtained from the Bureau of Soil Mechanics, NYSDPW.
1. Information required	* Review the list of minimum information for drill log, shown in Section 10, page 63, of Ref. B.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Use of information	* Indicate that analysis of the drill-hole log can supply considerable information to a highway designer.
1. Blows on drive pipe or casing	* State that the number of blows on the drive pipe is a very approximate indication of the driving resistance encountered by a pile.
2. Blows on drive sampler	* Mention that blows on drive sampler are an indication of the relative density of coarse-grain soils and an indication of the strength and consistency of fine-grain soils.
3. Field identification or description	* State that field description determines the types of soil and depths of various layers. Soil profiles may be developed from this information.
4. Ground water	* Relate that ground-water elevation is often an important consideration in design.
VII. NYSDPW Subsurface Exploration Organization	* Mention that the State Department of Public Works maintains about 35 drilling crews who do exploration work for highways and State buildings. * It is suggested that the instructor arrange to let the class examine a drill rig and other drilling equipment in conjunction with the portion of this lesson describing drill rigs. Arrangements may be made with the soils engineer in the local district office.

ASSIGNMENT

1. Study pages 418-453 of Ref. A.

Lesson 6 - Engineering Properties of Soils - Consolidation and Strength

REFERENCES CITED IN THIS LESSON

Hough, B. K. Basic soils engineering. New York. The Ronald Press Co. 1957. (Referred to in this unit by symbol "A")

Lambe, T. W. Soil testing for engineers. New York. John Wiley and Sons. 1951. (Referred to in this unit by symbol "F")

OBJECTIVES

1. To explain the consolidation characteristics of various types of soils under vibrational and static loading, and to review laboratory test procedures and methods of analyzing settlement problems

2. To explain the strength characteristics of various types of soils, including laboratory testing and analysis of stability problems

3. To discuss practical solutions used to solve consolidation and stability problems in highway design and construction

4. To review the methods used for determining the pressure distribution of applied loads on soils and the horizontal earth pressures on retaining walls

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Introduction	* Remind the class that in highway construction earth is used for the following purposes: 1. As a foundation to support embankments and structures 2. As an embankment construction material 3. To form cut slopes * Consolidation problems are involved with purposes 1 and 2. * Stability problems are involved with purposes 1, 2, and 3.
II. Consolidation of Soils	* Define consolidation as a decrease in the volume of a soil due to static

22367

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	weight of soil, shown as P_0 in Figure 6-3. 2. The additional load due to the applied fill is added to P_0 and shown as P_F in Figure 6-3. 3. The change in void ratio due to the added load (e_o - e_f) is determined from the laboratory test. 4. The total settlement in the field may be determined by using the following formula: $\text{Settlement} = \frac{H(e_o - e_f)}{1 + e_o}$ where H is the thickness of the compressible layer in the field.
5. Time for settlement	* Mention that the time for settlement in the field is a function of permeability and compressibility of the soil.
a. Analysis of test results	* State that time-consolidation relationships are indicated on a plot of compression vs. logarithm of time. * From the geometry of this plot, a constant called the coefficient of consolidation is determined. This is related to permeability. (Fig. 6-4)

Permeability constant for rate of consolidation derived from geometry characteristics of curve.

Constant is called Coefficient of Consolidation.

FIGURE 6-4
SOIL CONSOLIDATION CHARACTERISTICS:
COMPRESSION vs. LOGARITHMIC TIME PLOT FOR ONE LOADED INCREMENT
(Consolidation Test Data Obtained In Laboratory)

UNIT V (14.0302-07)

FINANCIAL ACTIVITIES

Performance Objectives:

Upon completion of this unit the student will be able to score at least 80% on an instructor developed objective test covering the handling and verifying of forms involved in ordering, receiving, selling, and general financial records. Also covered in this test should be common reports required by governmental agencies.

Unit Outline:

A. Importance of the Need of Financial Records

B. Types of Records

1. Personnel
2. Payroll
3. Sales and purchases
4. Inventory
5. Taxes
6. Financial Statements
7. Petty cash
8. Budgets
9. Credit applications

Supplemental Teaching Aids:

An excellent resource person for this unit is a staff member from the college business office. Free or inexpensive information is available from the Massachusetts Bankers Association, 125 High St., Boston, 12110. Of some value is the comic book-The Story of Checks, available from the Federal Reserve Bank of New York.

Training Time 8-10 hours

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

b. Computing time-settlement

* The details of computing time-settlement curves will not be covered in this course. The important factors to remember are:

1. Time required varies, since it is proportional to the square of the longest distance required for water to drain from the deposit. This distance is the thickness of the layer if all water drains vertically to the surface.

2. Time required for consolidation varies inversely as the coefficient of consolidation.

3. Rate of settlement decreases as time increases. Figure 6-5 shows a typical time-settlement curve for a clay deposit under embankment loading.

FIGURE 6-5
TIME-SETTLEMENT CURVE FOR FIELD PROBLEM

6. Summary

* It is suggested that the principal points of this section be reviewed before proceeding further.

* Emphasize that silt and clay soils will compress under loading. There is a time delay, while water flows from the voids, before settlement goes to completion.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
III. Strength of Soils	* State that the most important property of soils is strength. Slopes of all kinds, including hills, river banks, and man-made cuts and fills, stay in place only because of the strength of the material of which they are composed. * Note: A knowledge of soil strength is important for the design of structure foundations, embankments, retaining walls, pavements, and cuts.
A. Basic concepts	* Explain that a soil can derive its strength from two sources--friction between particles, and cohesion between particles. 1. Cohesionless soils, such as gravel, sand, and silt, derive their strength from friction between particles. 2. Cohesive soils, composed mainly of clay, derive their strength from the attraction, or bond, between particles. 3. Mixtures of cohesionless and cohesive soils derive strength from both friction between particles and cohesion.
1. Frictional strength	* Perform a simple demonstration of the idea of frictional strength by placing a block on a tabletop. Demonstrate and illustrate on the chalkboard.
a. Friction P_S = horizontal force P_F = frictional resistance	* Point out that a horizontal force is required to move the block and overcome frictional resistance. The frictional resistance is a function of the roughness between the two surfaces.
b. Normal force (P_N)	* State and demonstrate that an increase in the normal force P_N also increases P_F.

22375

FIGURE 6-6
BLOCK-ON-TABLE DEMONSTRATION: FRICTIONAL AND COHESIVE STRENGTH

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
c. Friction angle Φ	* When movement occurs, the angle from the vertical formed by the resultant of the normal-force reaction component and the frictional resistance component is called Φ, or the friction angle.
d. Frictional resistance	* The total available frictional resistance is equal to the normal force times the tangent of Φ. $P_F = P_N \tan \Phi$
e. Sloping surface	* Mention that if the table is tipped, the block will slide when the table is inclined at an angle to the horizontal equal to Φ.
	* State that a pile of dry sand will have an angle of repose of 30°. This is equal to the friction angle between soil particles (30°).
2. Cohesive strength demonstration	* Use the same block-on-table demonstration. This time there is an adhesive corresponding to cohesion in the soil, between the block and the table. If the horizontal force (P_S) is increased, the block will move suddenly when the cohesion is overcome. This indicates the strength of a clay is constant and results from the bond between particles. (Fig. 6-6)
a. Practical aspects	* The demonstrations show that the shear strength of granular soils increases as the load increases to a maximum amount determined by N tan Φ. The strength of a clay is constant and does not increase under a load. Therefore, clays are the more critical of the two soils for stability.
	* State that for practical purposes all clay deposits have some silt or sand mixed with them. Hence, under increased normal load there will be a slight increase in strength as the granular particles come in contact with each other when the soil consolidates.

22377

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Remind the class that the previous section on consolidation indicated there is a timelag for consolidation of clays which would also influence the rate of strength increase.
B. Strength testing	* Relate that the majority of strength tests are conducted on cohesive soils. Samples for testing are obtained from Shelby tube samples. It is very difficult to obtain undisturbed samples of noncohesive soils.
1. Unconfined compression test	* State that the unconfined compression test is the simplest and quickest laboratory method used to measure the shear strength of a cohesive soil.
a. Test procedure	1. A cylindrical specimen is placed on the testing machine and the load applied until the sample fails. 2. The unconfined compressive strength is one-half the applied load at failure, divided by the cross-section area of the sample. 3. Shear strength of soil is expressed in pounds per square foot (p.s.f.). 4. The test is conducted in the same manner as a compression test on a concrete cylinder.
2. Triaxial compression test	* Explain that the triaxial compression test is a strength test where the sample is subjected to confining pressures similar to those which existed in the ground before sampling. (See Fig. 6-7.)
a. Test procedure	1. The sample is trimmed to a cylinder 4 inches high and 1-1/2 inches in diameter. 2. The sample is covered with a thin rubber membrane and placed on a pedestal with a porous base for drainage.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	loading or vibrational forces applied to the soil mass.
A. From vibrational forces	* State that only loose, nonplastic, granular soils will consolidate from vibratory forces.
1. Structure of loose granular soils	* Indicate with sketch the structure of sand soil in loose condition and the same soil after consolidation. (Fig. 6-1)

Uniform Spheres Loose

Uniform Spheres Dense

Uniform Gradation

Well-graded Soil

FIGURE 6-1
STRUCTURE OF SOIL

2. Vibratory action	* State that vibration forces will cause soil grains to readjust into a more compact arrangement.
	* Mention that there is a type of compaction equipment operating on the vibration principle, which will be discussed in a later lesson.

22368

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Vibratory consolidation as a problem	* State that consolidation of soils from vibratory forces, such as heavy truck traffic, is not a problem so long as good construction practices are used to compact the soils under the pavement. * The magnitude of vibrational forces from traffic diminishes rapidly with depth below the pavement.
B. From static loading	* Define static loading as the permanent loads placed on the soil by embankments and structures.
1. Mechanics of consolidation	* Introduce by reviewing the basic concept of soil as consisting of soil solids, water, and air. (Fig. 6-1) * Most compressible foundation soils, being below the water table, have all the voids filled with water.
a. Load application	* State that load applied will cause soil grains to readjust to a more compact position in order to carry the load.
b. Escape of water	* Explain that this readjustment cannot take place until the water, which is incompressible, escapes from the voids.
c. Time delay	* In impervious soils, water will travel very slowly, and it may take years for the water to drain away from the loaded soil area so the settlement can go to completion.
2. Consolidation characteristics	* State that it is necessary to know what types of soils will be critical for consolidation for highway design.
a. Gravels, sand, and nonplastic silt	1. Gravels, sands, and nonplastic silts are relatively incompressible and will consolidate immediately when fill is placed. These soils do not present settlement problems.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
b. Plastic silts and clays	2. Plastic silts and clays are compressible. Soft silts and clays are more compressible than stiff silts and clays. Settlement may continue long after construction.
c. Organic soils	3. Organic soils are very compressible, and settlement of large magnitude will continue for years.
3. Consolidation test	* State that, in order to predict the amount of foundation soil consolidation under an embankment, it is necessary to determine the consolidation properties of the soils. * An undisturbed sample is obtained in the field with a Shelby tube sampler and brought to the laboratory for testing.
a. Consolidometer	* Explain and sketch the details of the consolidometer apparatus. (Ref. A, p. 101)(Fig. 6-2)
b. Test procedures	* Explain the test procedures as follows: 1. A soil sample is trimmed from the Shelby tube sample. Its dimensions are: diameter, 2-1/2 inches; height, 3/4 inch. 2. Loads are applied in increments at 24-hour intervals to cover the range of load intensity expected in the field. Loads are measured in pounds per square foot (p.s.f.). 3. The amount and rate of deflection are measured. 4. Complete drainage occurs in less than 24 hours, because of the short drainage distance the water travels to the porous plates.

22370

CONTENT OUTLINE TEACHING POINTS AND TECHNIQUES

FIGURE 6-2
CONSOLIDOMETER

c. Analysis of test results

* State that the compression characteristics are indicated on a plot of void ratio versus logarithm of pressure. (Fig. 6-3)

1. The curve indicates that there is very little change in void ratio or consolidation under loads up to the point of maximum past compression. This load is determined by the history of the forces acting on the clay in the past.

2. Above the point of maximum past compression, the clay is more compressible.

3. Clays having a point of maximum past compression equal to the existing overburden load are defined as normally loaded clays.

4. Some clays have been precompressed to loads above the

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

present overburden pressure. These are called preconsolidated clays. Preconsolidation may be caused by:

a. Overburden that has been eroded away in the past
b. Shrinkage forces due to drying

(Refer to shrinkage of clay in the discussion on plasticity, Lesson 3.)

FIGURE 6-3
SOIL CONSOLIDATION CHARACTERISTICS:
VOID RATIO vs. LOGARITHM OF LOAD (p.s.f.)
(Consolidation Test Data Obtained In Laboratory)

4. Application of results

* State that a series of consolidation tests is conducted for the total depth of a soil deposit to determine the average consolidation characteristics.

a. Amount of settlement

* Explain that the void ratio vs. logarithm of pressure curve is used to predict field settlements.

1. The existing pressure in the ground due to soil overburden may be determined from the unit

22372

UNIT VI (14.0302-08)

RECORD MANAGEMENT

Performance Objectives:

Upon completion of this unit the student will be able to score at least 90% of an objective test dealing with the techniques and mechanics of indexing and filing basic to records handling.

The student will be able to type names and code numbers on fifty cards and file the cards accurately in 40 minutes. She will be able to file accurately 60 to 90 pieces of correspondence in twenty minutes. She will be able to index a variety of documents having names, geographical locations, or numbers. For all of the preceding the student will be able to demonstrate quick and accurate retrieval methods.

Unit Outline:

A. Need for Filing

1. Information retrieval
2. Safe keeping
3. Storage

B. Types of Business Papers and Records Commonly Filed

1. Office
2. School
3. Home
4. Financial department files
5. Miscellaneous files

C. Filing Equipment Supplies

D. Nature of Business Records

1. Correspondence files
2. Personnel files
3. Inventory
4. Financial department files
5. Miscellaneous files

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

3. A pressure-tight lucite chamber and metal top fit around the sample.

4. An air pressure is applied in the chamber and the sample consolidates to its original void ratio.

5. The failure load is applied through a piston in the top cover.

FIGURE 6-7
TRIAXIAL TEST

b. Comments on test

* Explain that the triaxial compression test duplicates as accurately as possible the pressure conditions in the ground and gives an accurate indication of shear strength.

* State that the test is longer and more expensive than the unconfined compression test.

* Explain that a series of tests may be run under various confining pressures in order to determine the amount of strength increase with consolidation under embankment loads.

3. Vane shear test

* Explain that the vane shear test is a field test made in conjunction with drill-hole explorations in soft clays.

a. Equipment

* The vane consists of four fins spaced at 90°. The vane is 4 inches high and 2 inches in diameter. The apparatus is attached to the drill rods and pressed carefully into the

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	clay at the bottom of the drill hole. At the ground surface a lever arm applies torque and a force gauge measures the torque.
b. Operations	* The vane is rotated slowly until a cylinder of soil is sheared. The force gauge measures the torque, which can be converted into shear strength of the soil.
c. Comments	* This is a test for determining shear strength rapidly without laboratory testing. The results are accurate in soft silts and clays.
C. Presentation of strength results	* The strength results of the triaxial compression test are plotted on a Mohr's circle of stresses. This is used in determining strength of materials.
1. Mohr circle plot	* List the main points of a Mohr circle plot. (Fig. 6-8)
a. Shear stress (S)	* Mohr's circle is made on a plot of shear stress (in p.s.f.) vs. principal stress (in p.s.f.). * The principal stresses in a test are the confining pressure and failure pressure. They are plotted and used as a diameter for the Mohr circle. * A line drawn tangent to a series of Mohr circles is called the Mohr envelope and represents the maximum shear strength. The point of tangency of the envelope to any circle represents the shear strength for the combination of vertical and lateral pressures represented by that circle.
b. Friction angle ϕ	* The slope of the envelope line is equal to the friction angle ϕ.
c. Cohesion (C)	* The intercept of the Mohr envelope with the shear-stress axis is the cohesion. This is strength with no confining pressure; such is obtained from the unconfined compression test.

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

FIGURE 6-8
MOHR CIRCLE PLOT OF SHEAR STRENGTH

* The Mohr circle plot is useful in determining the strength of a soil for any pressure condition.

* The total shear strength at any overburden pressure is defined by

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

the equation:

$$S = C + N \tan\phi$$

where N is overburden pressure.

* Indicate typical envelopes for various soils. (Fig. 6-8)

D. Stability analysis

* Mention that the shear strengths obtained are used to perform stability analysis of embankments and structures.

1. Embankment stability analysis

* State that observations of many embankment failures involving the underlying foundation soils indicate that the failure surface is a circular arc. The embankment sinks down and the adjacent ground rises. (Fig. 6-9)

$$\text{Factor of Safety} = \frac{\text{(Resisting Moment)}\ \text{Total Shear Strength} \times L_s}{\text{Weight Force} \times L_w\ \text{(Overturning Moment)}}$$

FIGURE 6-9
EMBANKMENT STABILITY ANALYSES

CONTENT OUTLINE

a. Failure force

b. Resisting for

c. Mechanics of analysis

d. Factor of safe

IV. Design Solutions

A. Embankment stability problems

TEACHING POINTS AND TECHNIQUES

* Explain that the failure force consists of the weight of the embankment. The overturning moment is the product of the weight of the embankment (acting through its center of gravity) times the lever arm distance to the center of rotation (L_W).

ce * The resisting force against movement is the sum of all the soil shear strength acting along the failure arc. The resisting moment is the product of the shear strengths times the radius of the circle (L_S).

* For convenience, the width of the slice measured along the centerline is 1 foot. This simplifies computing total weight and total shear strength.

ety * The factor of safety against overturning is equal to the ratio of resisting moment to overturning moment.

$$\frac{\text{total shear strength} \times L_S}{\text{weight force} \times L_W}$$

* When the factor of safety is less than 1, failure will take place. The usual range of factors of safety used in design is 1.25 to 1.50.

* State that there are usually several solutions to a stability or settlement problem. The one chosen should be the most economical considering the following factors:

1. Available materials
2. Quantity and cost of materials
3. Construction time schedules
4. Line and grade requirements
5. Right-of-way

* Mention that the soil profile and soil properties have to be determined by explorations and testing in order to complete this final part of the analysis.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Relocate highway alignment	* State that a line shift of the highway to a better soils area may be the most economical solution.
2. Reduce grade line	* Explain that a reduction in grade line will decrease the weight of the embankment and may provide stability.

FIGURE 6-10
COUNTERWEIGHT BERMS

3. Counterweight berms	* Explain by using Figure 6-10 that the weight of the terraces, or berms, being on the outside of the center of rotation, provides an increased moment which resists failure. This increases the factor of safety.
4. Excavation of soft soil	* Mention that the strength of swamp soil is often insufficient to support embankments, and that in such cases soft soils are excavated and replaced with granular material.
5. Displacement of soft soil	* Indicate that for deep swamp deposits excavation is difficult and the swamp soil is displaced by continuous shear failures along the advancing fill front until the embankment is on firm bottom. The mudwave forced up in front of the fill is excavated to insure continuous displacement.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
6. Slow rate construction	* Mention that as a soil consolidates there is an accompanying increase in shear strength. For soils that consolidate relatively fast, such as some marls and silt-clays, this method is practical.
7. Lightweight embankment	* Point out that in some areas of New York State, for instance Buffalo, lightweight slag is available. This material weighs about 80 pounds per cubic foot. The overturning force is decreased by the lighter embankment weight.
8. Vertical sand drains	* Explain that vertical sand drains are usually the most expensive treatment and are not often used.

1. A sand drain is installed by driving a 12- to 18-inch diameter, closed-end casing to the bottom of the soft soil.
2. Clean, permeable sand is placed in the casing through a hopper with a pressure-tight gate.
3. When the mandrel is withdrawn, the bottom opens as a flap gate and the sand is forced out of the bottom of the casing by air pressure, leaving a column of sand in the ground.
4. Drains are installed at 8- to 12-foot centers, and a 2- to 3-foot layer of sand is placed for the full width of the embankment to permit drainage.
5. When the embankment is placed, the soil will consolidate if the water can drain from the voids. The soil water is initially under a pressure equal to the embankment weight pressure. This pressure forces the water laterally to the drains and upward through the permeable sand to the blanket.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	6. Sand drains diminish the time-lag for consolidation by reducing the drainage distance through the slow-draining soil.
	7. Sand drains accelerate settlement while increasing shear strength.
	8. Mention that a common point of confusion about sand drains is that the word "drain" usually implies downward drainage by gravity. In sand drains, the drainage is upward due to pressures in the soil water.
B. Embankment settlement problems	* Note that several of the methods for solving embankment stability problems also eliminate settlement.
	* State that embankments and pavements may undergo considerable foundation settlement as long as the settlement is uniform.
	* Objectionable differential settlements occur next to pile-supported structures.
1. Surcharge treatment	* State that the most common method is the surcharge treatment. The embankment is built up 1 to 10 feet above final grade elevation and allowed to remain for a determined waiting period. When the settlement with surcharge equals the estimated settlement without surcharge, the surcharge may be removed. (Fig. 6-11)
C. Stability and settlement problems for structure footings	* State that structure footings are designed with an allowable bearing capacity expressed in tons per square foot of footing. The allowable bearing capacity determines the size of footing for a design structure load.

CONTENT OUTLINE TEACHING POINTS AND TECHNIQUES

FIGURE 6-11
SURCHARGE TREATMENT

1. Stability requirements

* Explain that footings will fail with a circular-arc shear failure in the same manner as an embankment. Footings are designed with a factor of safety of three against shear failure. (Fig. 6-12)

FIGURE 6-12
FOOTING FAILURE

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Settlement requirements	* Indicate that the maximum allowable settlement of a footing is usually 1 inch. Settlement analysis may be made for each problem.
3. Design handbooks	* Explain that the above settlement and stability requirements have been worked into design tables using the blows on the drive sampler, with soil identification, for an estimate of strength and settlement.
V. Distribution of Pressure from Applied Loads	* The practical application of pressure distribution is used in analysis of embankment foundation settlement, footing pressures, and wheel loads.
A. Fundamentals	* Explain that the fundamental principle to remember is that the stresses from a surface loading spread out with depth. Picture a continuous footing on the ground surface with a unit load of 2 tons per square foot (t.s.f.). If the footing is 5 feet wide, the total load will be 10 tons. (Fig. 6-13) * Note that total load is the same at all depths. The <u>pressure</u> decreases with depth.
1. Pressure decrease with depth	* The load spreads out with depth. The approximate boundary of pressure distribution may be determined by a trapezoid with sides extending down at a 60° angle with the horizontal. This is often called the two-on-one method since, from the geometry of a 30°-60° right triangle, the line may be determined by going down two units and out one unit of measurement.
a. Pressure determination	* The vertical pressure on any horizontal plane at a given depth can be determined by dividing the total footing load by the area of the plane at the desired depth. For long footings, the length may be made 1 foot to simplify computations.

CONTENT OUTLINE TEACHING POINTS AND TECHNIQUES

FIGURE 6-13
PRESSURE DISTRIBUTION UNDER FOOTING

* Note that the total load on any plane is equal to the surface load, but the pressure intensity decreases with depth.

* The pressure intensity is the factor that influences settlement and shear failures.

B. Distribution under wheel loads

* Explain that wheel loads applied at the ground or pavement surface create a moving applied load which is roughly circular in shape. The load is distributed in circles of diameters that increase with depth.

* Discuss Figure 6-14 showing wheel-load pressure distribution.

1. The tire pressure of 100 pounds per square inch (p.s.i.) is comparable to the heavier construction equipment.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

2. At a depth of 12 inches, the pressure is one-fourth that at the surface.

3. At a depth of 36 inches the pressure is 6 percent of the surface pressure. This is comparable to the pressure exerted by a man standing on one foot.

FIGURE 6-14
STRESS DISTRIBUTION UNDER WHEEL LOAD

C. Significance of pressure distribution

* Mention that the rapid decrease in loading pressures with depth is an important reason why embankment layers should be placed in 8-inch lifts in order to obtain uniform compaction.

* The design of pavement foundations should have the materials with the highest strength immediately below the pavement. (Fig. 6-14)

E. Basic Rules for Alphabetic Filing

1. Terminology
2. Rules for indexing
3. Variations in names and applicable rules
4. Variations in company names and applicable rules
5. Special consideration-deviations from basic rules
6. Geographic location filing
7. Subject files
8. Cross-referencing

F. Basic Rules for Numeric Filing

1. Use of numeric files
2. Cross reference to alphabetic order
3. Chronological files

1. Identifying nature of information or document to be retrieved
2. Knowing the filing system
3. Computer or microfilm use

2208

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Constant head permeameter t = time for measured flow	* State that the quantity of water that flows through sample in a given time (t) is measured. From this information, Q is found. If i, t, and A are known, it is possible to compute k. (Fig. 7-3) * The constant head permeability test is used for pervious sands and gravels.

Q = Quantity of flow measured
i = Hydraulic Gradient - $\frac{h}{L}$
t = Time for measured flow
A = Cross-section area of soil sample

$$Q = kiAt$$

$$k = \frac{QL}{hAt}$$

FIGURE 7-3
CONSTANT HEAD PERMEABILITY TEST

2. Falling head permeameter	* State that the falling head permeability test is used for relatively impervious soils containing clay. * Because of the small volume of water that will flow, the quantity and head measurements are taken from a standpipe reservoir of small diameter.
3. Field tests	* State that the method of computing the permeability of the soil around a drill hole or well is to lower the water surface and measure the time required for the water surface to return to its original elevation.
4. Typical permeability values	* List values of the coefficient of of permeability for typical soils. The velocity of flow will be equal to the permeability when the hydraulic gradient is 1. Typical values:

22399

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	1. Clean gravel--10,000 feet per day 2. Clean sands, clean sand and gravel--100 feet per day 3. Fine sand--1 foot per day 4. Silt--0.01 foot per day 5. Silt and clay--0.0001 foot per day
E. Uses of permeability characteristics	* Cite engineering applications of permeability properties of soil, to wit: 1. Computation of seepage through earth dams and levees 2. Estimates of pumping capacity requirements for unwatering cofferdams or excavations below a water table 3. Spacing and depth of underdrains for lowering the water table under a roadway in order to improve subgrade stability
F. Effect of ground water seepage on soil stability	* Observe that we often see flowing water moving solid material, such as sand and pebbles, along the bottom of a stream. * Ground water flow has the same effect on a soil when there is sufficient force.
1. Quicksand experiment	* Perform, or illustrate on the chalkboard, the quicksand experiment. (Fig. 7-4) * Describe the mechanics of the experiment.
a. Seepage force	* State that when the seepage force caused by the head of water on the bottom of the sample equals the weight of the sample, a "quick" or "boiling" condition develops.

22400

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Water table	* Define the ground water table as the surface of free water in the ground.
1. Locating ground water	* The water surface in a well or boring will, after a time, show the true ground water table. The ground water level is difficult, sometimes impossible, to determine in impervious soils containing clay. In a drill hole, the elevation of the water used for drilling is frequently mistaken for a ground water surface.
2. Variation of ground water	* Mention that the surface of the ground water follows roughly the contours of the land. It appears at the ground surface in lakes, swamps, and streams. * State that the supply of ground water is continually replenished by precipitation soaking into the soil.
3. Perched water table	* Explain that in nature there is occasionally a dish-shaped layer of impervious material which holds the water above the main water table.
B. Ground water movement	* Indicate that ground water moves because of the difference in potential energy due to pressure and elevation above a chosen datum plane. (Ref. A, p. 65)
1. Pressure head	* Explain that if a standpipe is placed at a point in the soil the water will rise in the pipe above the point, if the water is under pressure. The height of rise is the pressure head, and it is usually measured in feet. Discuss Figure 7-2.
2. Elevation head	* Explain that the height of the point above a datum plane is called the elevation head and is also expressed in feet.

22396

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

3. Total head

* Point out that the total head is the sum of the pressure head and the elevation head.

Hydraulic Gradient =
(Pt. 1 to Pt. 2)

$$\frac{h}{L} = \frac{\text{Head Loss}}{\text{Distance}} = \frac{AD - BD}{DC} = \frac{AB}{DC}$$

Definition of Pressure Head and Elevation Head by Standpipe

Consider D-D as datum plane.

For Point 1

Pressure Head	- AC
Elevation Head	- CD
Total Head	- AD

For Point 2

Pressure Head	- BD
Elevation Head	- 0
Total Head	- BD

FIGURE 7-2
HYDRAULIC GRADIENT DEMONSTRATION

4. Head loss (h)

* Mention that the difference in total head loss between two points is termed the head loss and is usually expressed in feet and the letter "h."

* The head loss represents energy lost through viscous friction as water flows around the soil particles and through the irregular void passages.

5. Gradient

i = hydraulic gradient
L = distance flow

* State that the rate of head loss may be determined by dividing the head loss by the distance between the two points. This is called the gradient, and it has no dimensions. It is expressed as the letter "i."

$$i = \frac{h}{L}$$

6. Aquifers and artesian flow

* Define an aquifer as a soil layer in which flow of water is occurring. It usually consists of a pervious layer overlaid by a less pervious layer.

* Define artesian flow as the condition in which the static water pressure raises the water level in wells

22397

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	does not deflect, it has been estimated that the horizontal pressure coefficient will increase from 0.33 to 0.40 or 0.45.
	* Retaining walls have also failed when granular backfill has been placed loosely, with no compaction. Loose backfill will have a lower friction angle than 30°, and the horizontal pressure is increased.
B. Equivalent fluid pressure	* This term is often referred to in design books. It is the unit weight of soil multiplied by the horizontal pressure coefficient. For example, for a unit weight of 120 p.c.f. and a horizontal pressure coefficient of 0.33, the equivalent fluid pressure is 40 p.c.f. The triangular pressure diagram is obtained by multiplying the height of the wall by 40 p.c.f.
C. Importance of drainage	* If the backfill is not drained, the pressure against the wall may increase by 50 to 200 percent. Also, there may be additional thrust from frost action. This is the reason for providing drains at the back of a wall.
D. Pressure from clay backfill	* Mention that clays become plastic when wet. If the wall deflects, the clay will deform and continue to build up pressures on the wall over a long period of time.
	* The pressures on a wall from a wet, plastic clay backfill can be as much as nine times greater than the pressures from an adequately drained granular backfill.
	* Clays cannot be drained.
E. Wall failure	* Many retaining walls have failed because they were designed for granular backfill and clay was used in the field.

22392

ASSIGNMENT

1. Read Chapter 5 of Ref. A, on compressibility and consolidation, with special attention to sections 1, 2, 3, 6, and 14-18.

2. Read Chapter 6 of Ref. A, on shearing strength, with special attention to sections 1-3, 6, 10-12, and 19-21.

22393

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
VI. Horizontal Pressure on Walls	* Mention that all retaining walls must be designed to resist horizontal pressures.
A. Pressure from granular backfill	* Retaining walls will deflect very slightly when backfilled. This deflection will allow a triangular wedge of backfill to slide down against the wall. This is called the active pressure. (Fig. 6-15)

FIGURE 6-15
BACKFILL PRESSURE AGAINST WALL

1. Active pressure (1/3 WH)	* The active pressure which acts against the wall is one-third the unit weight of soil (W) times the height of soil (H). One-third represents the horizontal pressure coefficient for a soil friction angle of 30°. This coefficient is different for soils other than granular backfill. Since walls are backfilled with granular material, a friction angle of 30°, which gives a lateral pressure coefficient of one-third, is reasonable. This applies only if the ground surface is horizontal and if there is no surcharge loading behind the wall. If the wall

C. Darcy's Law

v = velocity

1. Coefficient of permeability (k)

2. Quantity of flow

Q = quantity in cubi feet of flow, measured per day minute, or secon

A = cross-section area of flow analyzed

D. Measuring permeability

TEACHING POINTS AND TECHNIQUES

or drill holes above the ground water table. The popular definition for artesian flow is a condition in which the water level rises above the ground surface.

* Explain that Darcy's Law is an important principle in hydraulics, stating that for flow of water through soil the velocity or flow is proportional to the gradient: (Ref. A, p. 66)

$$v \text{ is proportional to } i$$

* State that the constant of proportionality is expressed as "k" and is called the coefficient of permeability. It is used thus:

$$v = ki$$

* State that the coefficient of permeability can be expressed in feet per day, feet per minute, or feet per second.

* State that the range of k varies with the type and density of soil. The coefficient of permeability for a clean gravel is over one million times the value for a clay. The large range in k explains the variable time units used.

* State that quantity flow may be determined from the formula:

$$Q = Av = kiA$$

* Mention that both laboratory and field procedures are used to measure permeability characteristics.

22398

Lesson 7 - Soil Water

REFERENCE CITED IN THIS LESSON

Hough, B. K. Basic soils engineering. New York. The Ronald Press Co. 1957. (Referred to in this unit by symbol "A")

OBJECTIVE

To acquaint the student with the types of soil water, the behavior of soil water, and its influences on the design, construction, and performance of highways

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Introduction	* Mention that the presence of water in the soil mass plays an important part in determining the engineering characteristics of the soil. A change in water conditions can result in a rapid change in soil strength.
A. Types of soil water	* State that this lesson will define and discuss three types of soil water. (Ref. A, Chap. 3) 1. Free, or ground, water is controlled by the force of gravity. 2. Capillary water is controlled by the forces of capillarity. 3. Absorbed water consists of very thin layers of water attached by molecular attraction to the soil surface. This is also called hygroscopic water. * Discuss Figure 7-1, showing the types of soil water.
II. Ground Water	* Define ground water as that water in the soil that is completely free to move through or drain from the soil under the influence of gravity. (Ref. A, p. 62)

22394

J. Retention and Purging of Files

1. Permanent record identification

2. Length of retention

3. Active and inactive files

4. Transfer and storage

Supplemental Teaching Aids:

Good resource people for this unit are school librarians or bank employees. A visit to a local library to observe its filing system is useful also.

The following are good resource books for the unit; Business Filing and Records Control, 3rd ed., Ernest D. Bassett, South-Western, Cincinnati, 1963, Records Management, Mary C. Griffin, Allyn and Bacon, Boston, 1964, and Gregg Quick Filing Practice, McGraw-Hill, New York, 1965.

A useful programmed instruction book is Basic Rules of Alphabetic Filing, by Fahrner and Gibbs, South-Western, Cincinnati, 1965. Free or inexpensive pamphlets are available from Smead Manufacturing Co., Hastings, Minnesota (Do's & Dont's of Filing and Science of Filing), and from the Oxford Filing Supply Company, Inc., Garden City, N. Y. 11533 (33 Common Filing Questions). Remington Rand, Systems Division has the film "It Must be Somewhere", while Cornet Films has "Filing Procedures in Business".

Training Time 30-40 hours

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

FIGURE 7-7
FROST HEAVE AND FROST BOIL IN SOIL
(Source: Ref. L, p. 309)

a. Frost boils

* Frost boils are the areas where pavements break up due to loss of subgrade support. Frost boils may last as long as several weeks until the soil thaws completely and the excess water can drain. Extensive frost boil conditions can develop in one day after a period of thawing weather.

B. Cause of frost heave

* Assert that the early belief was that frost heaving was caused by the expansion of water in freezing. Since freezing causes only a 9 percent volume increase, it did not explain frost heaves two feet high.

1. Growth of ice layers

* Ice layers grow in the following sequence (Fig. 7-7):

1. Pore water is frozen directly under the pavement.
2. The freezing causes a pressure decrease in the capillary forces of soil water. This decrease in pressure attracts capillary water from below, which forms additional ice crystals. The lenses will continue to build up as long as:

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

a. Freezing conditions continue
b. There is a water table to supply water
c. The water can be carried by capillary forces to the ice lenses

C. Control of frost heaving

* State that frost heaving can be controlled by removing the factors that cause it and determining the potential areas of frost heave during design.

1. Coarse-grain subbase

* Explain that heaving can be eliminated if a layer of clean sand and gravel is placed to a depth greater than the maximum depth of frost penetration. Tests indicate that the material must not have more than 3 percent of content finer than 0.02 mm., which is a very clean gravel. This treatment is quite expensive.

2. Lowering water table

* Ditches may be used to lower the water table and increase the vertical distance necessary for capillary rise between the water table and the pavement.

D. Critical soils for frost heaving

* Mention that most frost heaves occur in cuts.

* The most critical soils in frost heave are silt deposits that overlie water-bearing sands or gravels.

1. Moraine deposits

* Remind the class that moraine deposits are irregular mounds of debris left at the edge of the receding ice sheet. They often contain pockets of silt adjacent to coarser water-bearing soils. Kames are in the same category.

* A survey in Michigan indicated that about two-thirds of the detrimental frost heaves occurred in moraine deposits.

2. Other deposits

* Frost heaves do not occur in clay deposits, since the capillary flow of water in these is extremely slow.

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

* Frost heaves do not occur in clean, coarse sands and gravels, where the capillary rise is low.

* Frost heaves can occur in soils where the capillary properties are strong enough to carry the water from the water table to the zone of freezing.

* In the Adirondack Mountains, frost heaves are common at the transition into rock cuts. Ground water flowing off the surface of the rock creates the necessary conditions for heaving.

E. Frost heaving phenomena

1. Shallow culverts

* Culverts are raised by the movement of freezing soil adjacent to the pipes. The depth of frost penetration adjacent to a culvert increases as cold air circulates through the culvert. As the pipe heaves, a void forms under the bottom. When the soil thaws, material fills the void so that the culvert cannot subside with the surrounding soil. The result is an objectionable bump in the road.

2. Boulders

* Farmers have found that new boulders appear in their fields each year. These are brought to the surface by the same action described for culverts. Boulders are also pushed through pavements, forming bumps. Boulder undercutting is used on new construction in northern New York State.

3. Structures

* Foundations for major structures are placed below frost depth to avoid heaving.

ASSIGNMENT

1. Read all of Chapter 3, Ref. A.

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

FIGURE 7-4
QUICKSAND EXPERIMENT

b. Submerged weight of sand

* The seepage force is the force imparted to the soil by the flow of water. As the void size and particle size decrease, there will be more frictional resistance to the flow which acts as a force on the soil mass. The direction of the seepage force is always in the direction of flow. The magnitude of the force is $i\gamma_w$. This is the force acting on each cubic foot of soil. In the quicksand experiment, the submerged weight of sand is about 60 pounds per cubic foot. The upward seepage force is 62.4 pounds per cubic foot when i = 1. The critical hydraulic gradient of 1 will cause a "quick" condition in a fine sand.

2. Quicksand conditions

* Mention that quicksand conditions are most likely to occur in fine sands and nonplastic silts. They very seldom occur in coarse sands or gravels.

a. Critical soils

* Explain, from the basic relation v = ki. The coarser granular soils have coefficients of permeability 100

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

times, or more, that of the finer sand and silt soils.

b. Occurrence of "quick" conditions

* Mention that quicksand can occur in nature in the bed of a lake or river where ground water flows upward under artesian pressure.

* Describe "quick" conditions in construction, viz:

1. In cut excavations
2. In unwatered excavations for footings of buildings or bridges
3. On the downstream side of dams after the reservoir has been filled

* Mention the popular misconception of quicksand as a type of soil deposit. Actually it is a temporary instability of a soil caused by water conditions.

* People caught in quicksand will not sink if they remain still.

c. Prevention of sand boils

* State that the usual method to stabilize a "quick" area is to cover it with a blanket of gravel which will add weight to the soil. Since the permeability of the gravel is many times that of the sand, the hydraulic gradient in the gravel will be reduced below the critical value of 1. Explain from the equation v = ki.

* Another method is to build a ring of sand bags around the area, allow the water to pond, and make a back pressure which reduces the hydraulic gradient and quiets the soil. Barrels have been used to control small boils.

3. Compaction by puddling

* Mention that an old method of compacting excavation backfills was puddling. As the excavation was backfilled the trench was flooded with water. The downward seepage force of the water supposedly compacted the backfill.

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

a. Conditions needed for compaction

* Explain that in order for any compaction to take place the following conditions must be present:

1. The backfill has to be permeable enough to allow reasonably rapid drainage.
2. The surrounding soil has to have a permeability equal to or greater than the backfill.

b. Puddling not recommended

* Point out that puddling is not recommended for compacting excavation backfill, because the relative permeabilities of the backfill and surrounding soil are difficult to estimate. Success depends on the right combination of permeabilities, which does not always exist.

4. Ground water seepage on cut slopes

* Explain that where concentrated zones of ground water seepage emerge on a cut slope seepage forces may cause the soil to become "quick" and flow down the slope.

a. Typical critical soil conditions

* Inform the class that this condition often exists where a fine sand or silt overlies an impervious soil, such as clay.

* Concentrated horizontal ground water flow along the top of the impervious layer emerges on the cut slope at a velocity great enough to make the fine sand or silt "quick." The condition of instability works back from the cut surface and undermines the slope above.

b. Gravel slope protection blanket

* Indicate that the treatment for this problem is to place a 2- or 3-foot gravel blanket from the zone of seepage to the bottom of the slope. Often the lower slope will erode from the concentrated flow on its surface. The requirements of this gravel blanket are:

1. A permeability great enough to reduce the hydraulic gradient

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	causing instability (v = ki relations)
	2. Sufficient fine material to make voids in the gravel blanket small enough to prevent fine sand and silt from washing in and clogging the voids
c. NYSDPW use of granular blanket	* The New York State Department of Public Works uses a granular slope-protection blanket item with a gradation that satisfies the above two requirements.
III. Capillary Water	* Explain that above the water table is a zone where the soil voids are filled with capillary water. In contrast to the ground water, which is controlled by the forces of gravity, capillary water is controlled by the forces of capillarity. (Fig. 7-1) (Ref. A, p. 56)
A. Capillarity demonstration	* Illustrate or demonstrate a small-bore tube inserted in water. The water rises a distance inside the tube. Experiments with tubes of various sizes show that the capillary rise increases as the diameter decreases. (Fig. 7-5)
B. Explanation of capillarity	

$$\text{Capillary Force} = \frac{2T_s}{R}$$

$$\text{Wt. Water in Column} = h_c \gamma_w$$

$$h_c = \frac{2T_s}{\gamma_w R}$$

FIGURE 7-5
CAPILLARY RISE

22404

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Surface tension	* Explain that the force holding up the column of water is surface tension. It is a property of liquids that the molecules at the surface are in tension and appear to act like a stretched membrane.
2. Wetting property of water	* Explain that water tends to wet surfaces with which it comes in contact, resulting in a curvature of the water surface.
3. Capillary rise H_c = height of capillary rise T_s = surface tension R = radius of tube	* Show that surface tension force, acting along a radius of curvature results in a vertical component of force. This force is equal to and supports the weight of the column of water in the capillary rise. From this relation it can be determined that: $H_c = \frac{2T_s}{\gamma_w R}$ * The most important thing to remember is that the height of capillary rise varies inversely as the radius of the tube or soil void.
C. Practical aspects	* Capillary rise and the forces of surface tension influence greatly the properties of soils. * Consider the voids in a soil sample to be similar in shape to a series of small, winding, irregular capillary tubes. * Plants and trees lift water from their roots to the leaves in small capillary tubes.
1. Greatest rise in fine-grain soils	* It has been demonstrated that the height of capillary rise varies inversely to the radius of the soil pores. The fine-grain soils have the smallest pores and therefore the greatest capillary rise.

22405

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	becomes free water, the pile of sand will diminish in volume. Bulking may increase the volume of sand by as much as 25 percent.
3. Effect on beach sands	* Describe the behavior of sand beaches, which can support heavy traffic when damp but will rut badly when dry. 1. When soil is dry, concentrated wheel loads will exceed the shearing strength of the granular material, and failure of the soil, or rutting, will occur. 2. After high tide recedes, the sand will drain. Tightly held capillary films develop at the contact points between particles, drawing the soil together and resulting in high shear strength. As the particle sizes decrease, the void diameters decrease and the capillary strength increases.
IV. Construction Drainage	* Mention that an understanding of the behavior of soil water movement is important when excavating cuts and making excavations for structure foundations.
A. Ground water control	* Repeat that ground water is controlled by gravity.
1. Ditches and dumping	* Drainage can be accomplished with ditches in cuts and pumping in excavations.
2. Well points	* Mention that well points are used where there are large quantities of water to remove or where excavating conditions are difficult in wet soils. Well points are pipes with perforated and screened end sections driven or jetted to an elevation below the bottom of proposed excavation. The pipes are connected to a pumping system and the

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

water surface is lowered by pumping. Well points are not effective in silt soils or clay soils due to the low permeability of the material. (Fig. 7-6)

FIGURE 7-6
WELL POINTS

3. Cuts in water-bearing soils

* State that cuts should be made on an upward grade to allow drainage. Cuts made on a downgrade will collect water at the excavation face.

B. Surface water control

* Mention that ditching and drainage grading should be maintained in all cuts to provide drainage for surface runoff. Ponding of water and saturation of soils make all soils except highly pervious materials difficult to handle during construction. Surface water may be controlled by gravity drainage.

C. Problem soils for drainage

* Explain that the effectiveness of drainage varies with the properties of the soils encountered.

1. Silts

* State that silts may be difficult to drain by ditches when the capillary rise above the water table is greater than the practical depth of a ditch.

22408

UNIT VII (14.0302-06)

SOURCES OF INFORMATION

Performance Objectives:

Upon completion of this unit the student will be able to demonstrate her knowledge of information sources by compiling a list of information to meet specifications designated by the instructor.

Unit Outline:

A. The Reference Book as a Tool of the Office Worker

1. Importance of accurate business information
2. Kinds of information needed
3. Necessity of obtaining information quickly
4. Necessity for initiative in finding information

B. Reference Books of the Office Worker

1. Dictionaries
2. Reference manual for stenographers and typists
3. English grammar and style books
4. Directories
5. Thesaurus

C. Other Sources of Factual Information

Supplemental Teaching Aids:

The most obvious resource person is of course the librarian. Also available is the Gregg Secretarial Record #6, Set #2 "Finding Needed Information". The film "Look It Up-Dictionary Habits" (11 min.) is available from Cornet Instructional Films.

Training Time 3-5 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Clays	* Assert that ground water control is not a problem with clays because the soil is impervious and there is little ground water. The big problem is to provide drainage for surface runoff, as the soil will lose strength from soaking in ponded water.
3. Sands and gravel	* Point out that sand and gravel deposits may have water-bearing layers, or lenses, that provide water in large quantities. Special drainage may be required for these areas.
4. Soil mixtures	* Explain that the majority of soils contain mixtures of the above soils in various proportions. It will take observation and judgment to determine whether the properties of silt, clay, or granular materials are influencing the behavior of soil water in excavations.
V. Frost Action in Soil	* State that damage to pavements by frost action is one of the most difficult soil problems to solve. Such damage may be serious and expensive to repair. (Ref. A, p. 77)
A. Phases of frost damage	* Mention that frost damage to pavements occurs in two distinct phases.
1. Pavement heave	* State that, as the frost line penetrates the soil beneath a pavement, ice may form in areas where soil and water conditions are favorable to their growth. The depth of frost penetration in New York State varies from 1 foot on Long Island to 4 to 6 feet in the upstate. (Fig. 7-7)
a. Differential heaving	* Uniform heaving is not objectionable. When soil conditions are not uniform, differential heaves of several inches to 2 feet can occur.
2. Thaw period	* State that thawing works from the surface down. Soil becomes supersaturated because it cannot drain, and loses all strength.

22409

OBJECTIVE

To explain the principles of soil compaction and the field procedures and equipment used to obtain proper soil compaction

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Introduction	* State that compaction is one of the most important lessons in this course, as most technicians will perform or supervise earthwork inspection at some time in their careers.
A. Proper compaction for pavements	* Proper compaction of embankments and backfills is an essential factor contributing to a smooth-riding pavement.
B. Need for knowledge of compaction principles	* Knowledge of the principles of compaction and the behavior of types of soils under varying field conditions

22413

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	is necessary to an understanding of the problems a field inspector will encounter.
II. Fundamentals of Soil Compaction	* Define compaction as the process of artificially densifying a soil by pressing the soil particles together so that air and water are expelled from the soil mass.
A. Method of densification	* State that densification is achieved by applying moving loads to the soil mass.
	* Explain that the dynamic compaction of moving loads is different from the compaction of foundation soils by static loading (embankment loads), discussed in Lesson 6.
B. Advantages gained from compaction	* Mention that the advantages gained from compaction have made it a standard procedure in the construction of highways, earth dams, and airports.
1. Minimizing settlement	* State that densification by compaction will prevent later consolidation of the embankment soil from static and moving traffic loads and from the weight of the overlying embankment material. (Fig. 8-1)

FIGURE 8-1
EMBANKMENT SETTLEMENT vs. DENSITY

22414

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Point out that embankment compaction will not eliminate the settlement caused by consolidation of deep underlying compressible soil layers which form the foundation for the embankment (discussed in Lesson 6).
2. Increased shearing resistance	* Explain that increasing density by compaction will increase the shearing strength of a soil. (Fig. 8-2) Pavement failures can occur if the supporting soil has insufficient strength.

FIGURE 8-2
EMBANKMENT STRENGTH vs. DENSITY

3. Effects on water movement	* State that the densification of a soil will lessen the water movement by reducing the number of void spaces and the sizes of voids.
a. Reduction in permeability	* Inform the class that reduction in permeability will decrease the water movement or seepage in the soil mass. This minimizes the tendency for the soil to take up water and suffer later reductions in strength.
b. Reduction in air space	* Remind the class of the principle of capillary flow and the need for air in voids to develop capillary movement of water. A reduction of air in the soil diminishes the possibility of water increase by capillary flow.
c. Importance	* Emphasize that decreasing the tendency for water movement in the zone of the embankment immediately below

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	the pavement is very important. The surface portion of the embankment is subject to infiltration from precipitation and the effects of freezing and thawing, all of which tend to increase the moisture and decrease the shear strength.
C. Factors influencing density	* Mention that there are three fundamental factors that influence the density of a compacted soil.
1. Compactive effort	* State that compactive effort is the energy used per unit volume of soil for densification. * Factors influencing the compactive effort are: 1. Layer thickness 2. Type and weight of equipment 3. Number of passes of equipment * Mention that these factors will be discussed in detail in a later section.
2. Type of soil	* List the various soil properties affecting compaction: 1. Size of soil particles 2. Gradation of soil particles 3. Shape of soil particles 4. Plasticity of fine-grained particles 5. Specific gravity
3. Moisture content	* State that the moisture content of soil at compaction is one of the most important factors influencing the soil density.
D. Moisture-density relation	* Show, using Figure 8-3, that for each soil a maximum dry density is developed at an optimum moisture content for the compactive effort used.
1. Optimum moisture content	* Define optimum moisture content as the moisture content at which a soil has a maximum dry density for the compactive effort used.

22416

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

FIGURE 8-3
BASIC COMPACTION CURVE

2. Mechanics of moisture-density relation

* Explain the mechanics of the compaction as follows:

1. When soil is dry, soil grains pressed together will rebound.
2. When soil is very wet, the water in the voids interferes with the packing of particles. The particles will slide over one another instead of packing.
3. When a soil is at the optimum moisture content, there is sufficient water to lubricate the particles. They will slide over one another and hold in place in the closest-packed arrangement for the given compactive effort.

3. Laboratory compaction tests

* Indicate that two standardized compaction test procedures are used in the United States.

a. Standard AASHO

* State that the standard AASHO (American Association of State Highway Officials) compaction procedure is used by most state highway departments. (Ref. F, Chap. 5)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Describe the test procedures: 1. Soil is compacted in mold 4.6 inches high, 4 inches in diameter, with volume of 1/30 cu. ft. 2. Soil is placed in three layers. 3. Each layer is compacted with 25 blows of 5 1/2-pound hammer falling 12 inches. 4. Compactive effort is 12,400 foot-pounds of energy per cubic foot of soil.
b. Modified AASHO	* State that the modified AASHO compaction procedure is used by the U.S. Corps of Engineers and several state highway departments. * Describe the test procedure: 1. Soil is compacted in same mold as used for standard AASHO test. 2. Soil is placed in five layers. 3. Each layer is compacted with 25 blows of a 10-pound hammer falling 18 inches. 4. Compactive effort is 56,200 foot-pounds of energy per cubic foot of soil.
c. Test procedure	* Indicate that to develop the moisture-density relationship several samples of the soil at various moisture contents are compacted. The wet unit weights and moisture contents are determined and the dry unit weight corresponding to each moisture content is calculated. The points are plotted on a moisture-dry density curve. (Fig. 8-3)
4. Zero-air-voids ratio curve	* State that the zero-air-voids ratio curve represents the theoretical dry density of the sample if all the air is expelled from the voids. This curve may also be called the 100 percent saturation curve. (Remind the class that the saturation is $\frac{V_w}{V_v}$ expressed as a percent.)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
a. Significance of curve	* Explain a sketch, showing lines of 80 and 90 percent saturation. (Fig. 8-4) * At moisture contents above the optimum moisture content the moisture-density curve is parallel to a percent-saturation line. * The positions of the curves indicate that as water is added beyond the optimum moisture content, a certain volume of air is entrapped in the voids that no amount of compaction or addition of water will remove.
b. Use of curve	* State that the zero-air-voids ratio curve serves two practical purposes: 1. If any values of the dry density curve are plotted to the right of the zero-air-voids curve, there must be an error. The error may be in the test measurement, the calculation, or the specific gravity. 2. The zero-air-voids ratio curve serves as an aid to drawing the moisture density curve, since they are parallel.
E. Variables affecting moisture-density curve	
1. Variation of compactive effort	* Explain that, for all soils, in field or laboratory compaction, an increase in compactive effort will increase the maximum dry unit weight and decrease the optimum moisture content. (Fig. 8-5)
2. Compaction characteristics	* State that the moisture-density curves for each type of soil will vary in shape and location on the graph. * These variations are influenced by grain size, gradation, particle shape, plasticity, and specific gravity.

FIGURE 8-4
BASIC COMPACTION CURVE AND PERCENTAGE OF SATURATION

Compactive Effort increases from CE 1 to CE3.

With increase in Compactive Effort, maximum density increases and optimum moisture content decreases.

Soil Type is same for all tests.

FIGURE 8-5
EFFECT OF COMPACTIVE EFFORT ON MOISTURE-DENSITY CURVE

Soil Type varies.
Compactive Effort constant.

FIGURE 8-6
EFFECT OF SOIL TYPE ON MOISTURE-DENSITY CURVE

22420

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Illustrate, using Figure 8-6, the position and shape of typical curves.
a. Effect of gradation	* Explain that a well-graded soil whose grain sizes vary from coarse to fine gives the highest density.
	* The smaller particles fill the voids between larger particles.
	* Well-graded materials are sensitive to changes in moisture when compacted, and their curves have sharp peaks.
	* Uniform soils, whose particles are all the same size, are slightly sensitive to change in moisture content, and their moisture-density curves have only slight curvatures.
b. Effect of particle size	* Explain that, in general, the coarse-grain soils will have higher densities than the fine-grain soils.
	* Sometimes the factor of gradation may mask this trend.
3. Effect of temperature	* Point out that it is very difficult to compact soil when the temperature is below 32° F., because there is no water to lubricate particles and allow the mass to densify.
III. Compaction Requirements for Embankments	* Mention that the compaction requirements to be discussed are those specified by the New York State Department of Public Works in its construction specifications. All agencies have compaction specifications, most of which contain all or some of the New York requirements.
A. Layer construction	* Mention that soil should be placed in layers no more than 8 inches in thickness before compaction.
1. Purpose	* Layer construction is intended to insure that the soil is uniformly compacted with depth.

DOT #209.388

TRAINING COURSE FOR

CLERK-TYPISTS

The material in this guide is presented in the form of suggestions. Every student participating in this program will be different in regard to education, experience, and ability. The instructor must, therefore, adjust and adapt the suggestions in this guide to the needs of individual students.

The first step in insuring this adjustment is to secure as much information as possible about each new student. This can be accomplished through study of the pre-enrollment information gathered by the Center counselors. The second step is to keep up to date on the progress of each student through the regular use of the information prepared by Individual Program Control (IPC). With this information on hand the instructor can effectively adapt specific objectives, teaching methods, and time alloted to each aspect of the training, directly to the student't needs.

This guide will aid the instructor in accomplishing part of his job. It will provide performance objectives, suggest time allotments, unit outlines, and supplemental teaching aids. Only the instructor, however, can combine these factors with a knowledge of each individual student.

Course Objectives:

The Clerk-Typist program at Gila River Career Center is designed to:

1. develop in the student an awareness of the importance of office work and of the career opportunities which it offers.

2. develop an understanding of the place and purpose of the office in general, and the clerk-typist in particular, in the typical business organization.

3. develop a job-centered approach to businesslike work habits and attitudes and effective human relations.

4. prepare the student to perform the fundamental tasks commonly required of all beginning office workers.

5. prepare the student to perform the technical tasks commonly expected of the clerk-typist.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Field tests	* Mention that field tests have been conducted to determine the effectiveness of compaction with depth. Pneumatic-tired rollers were used. The unit pressure decreased rapidly with depth. At a depth of 12 inches the roller pressure on the soil was about 50 percent of the surface loading intensity. (Ref. G, p. 68) (Fig. 8-7) Even the heaviest compaction equipment will not give uniform compaction with depth.

FIGURE 8-7
PRESSURE DISTRIBUTION BELOW PNEUMATIC-TIRE ROLLER WHEEL
(Source: Ref. G, p. 68)

B. Number of roller passes	* Indicate that a minimum number of six passes is required for full coverage of each embankment layer.
1. Field tests	* Assert that field tests indicate that the density increases rapidly with the first few passes. There is practically no increase in density after about 10 passes. (Ref. G, p.54) (Fig. 8-8)
	* Explain that six passes give the density required for sufficient compaction.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES

FIGURE 8-8
EFFECT OF NUMBER OF ROLLER PASSES ON COMPACTION
(Source: Ref. G, p. 69)

C. Embankment density	* Embankment density is expressed as a percent of the maximum density set by the AASHO test.
1. Requirements	* A minimum embankment density of 90 percent of maximum is required.
	* For sand, or a sand and gravel mix, with less than 20 percent fines (material passing No. 200 sieve), a minimum embankment density of 95 percent of the maximum density is required.
D. Moisture content control	* Fill material must have a moisture content not less than 3 percent drier than the optimum set by the AASHO density test. Water can be added to soil and mixed by blading or harrowing. (Ref. H, p. 200)
	* State that wet soils which cannot be properly compacted may be dried by aeration or by the addition of dry material. Aeration is hastened by discing, harrowing, or blading.
	* Drying is most effective when the maximum surface area of the soil is exposed to the air.
E. Type of compaction equipment	* State that the type of compaction equipment for various types of soil is specified, including minimum unit contact pressures.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
IV. Compaction Equipment	* Explain that there are several different types of compaction equipment. The type of soil to be compacted determines what type of equipment will be most efficient. (Ref. A, p. 396)
A. Smooth-wheel roller	* State that the smooth-wheel roller was the earliest type developed. Its usual weight is 10 tons.
1. Uses	* Mention that New York State specifications require that the smooth-wheel roller be used to compact rock, coarse gravel, soil and rock, and slag.
	* Add that the roller is used to compact base courses and to seal the fill surface to expedite runoff of rain.
B. Sheepsfoot roller	
1. Origin	* Describe the features of the sheepsfoot roller and explain that its design was based on the observation that sheep or cattle paths become very compact from the passage of many hooves.
2. Use	* Explain that sheepsfoot rollers are used to compact fine-grain soils composed of silt, or of silt and clay.
3. Effectiveness	* Discuss the advantages of high unit pressures of 100 to 250 pounds per square inch developed by the tamping feet. Mention the following points:
a. Kneading action	1. Compaction is obtained from the pressures on the tamping feet and the kneading action of the tamping feet.
b. Walking out	2. The soil is compacted from the bottom of the layer upward. After each pass, the feet should ride higher on the soil. This effect is called walking out.
c. Clay	3. The roller is effective in breaking up chunks of clay.
d. Granular soil	4. Warn that in granular soil the tamping feet tend to tear and displace the soil instead of giving compaction.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
e. Stony fill	5. In stony soils the tamping feet will not penetrate.
C. Grid roller	* Explain that the grid roller is a recently developed type of roller made in grid sections, formed by 1-1/2-inch round bars with 3-1/2-inch spaces between them. * The action of the roller is similar to that of the sheepsfoot roller, as the total weight is applied at contact points under high unit pressure.
D. Rubber-tired or pneumatic-tired rollers	* Describe the features of the rubber-tired roller. * Mention that the size of these rollers has increased in the last 20 years. Thirty- and 50-ton rollers are common. Tire pressures are about 80 pounds per square inch.
1. Use	* Point out that the pneumatic-tired roller is used to compact granular soils, such as sands and gravels. Granular soils compact best when they are confined under a larger load area and compressed.
2. Versatility	* State that this is the most versatile roller, since the action of the tires combines kneading and rolling properties.
E. Vibratory rollers	* Mention that rollers are manufactured using vibratory equipment to increase the effectiveness of compaction.
1. Effect of vibration on compaction	* State that the particles in a soil mass will vibrate when subjected to a vibratory force of a certain frequency (cycles per second).
a. Natural frequency	* Each soil mass has a natural frequency at which the soil particles will vibrate. The natural frequency depends on the properties of the soil.

22425

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
b. Frequency range	* The range of natural frequencies for soils varies from 18 to 30 cycles per second.
c. Compaction	* The combination of a static load with vibrations at the natural frequency of the soil will allow the soil grains to readjust and densify to a smaller volume.
2. Use	* State that vibratory compaction is most effective in granular, non-plastic soils.
3. Types of equipment	* Describe the types of equipment. (Ref. A, p. 400)
4. Comparison to bulldozers	* Mention the frequent argument that bulldozers compact soils by vibration. The unit load under the tracks is low and it is doubtful that the vibrations have an effect on the soil which will result in satisfactory compaction for highway embankments.
F. Small compaction units	* Explain that for compacting backfill in close quarters around structures small portable compaction units are used.
1. Tampers	* Tampers are powered by gasoline motors or by compressed air. Describe them.
	* The minimum compaction energy per blow is stated on page 201 of Ref. A.
V. Inspection Control of Embankment Construction	* Emphasize that to properly inspect and control embankment construction it is necessary to read and understand the specifications pertaining to earthwork. (Ref. I)
A. Intelligent inspection	* State that intelligent inspection depends upon a knowledge of the specifications, an understanding of the behavior of various types of soils, the ability to observe, and commonsense.

22426

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Uniformity of results	* The goal of embankment construction is to provide a smooth-riding foundation for many miles. This can be achieved only by providing a stable and uniform embankment. One of the best ways to achieve a uniform embankment is for the contractor to develop an efficient operational procedure, and to see that it is adhered to by continual checking. Visual observation by the inspector can determine whether the routine is producing the required results at all times.
C. Importance of testing	* Field density tests reveal whether the compaction requirements are being obtained. The tests can be run on only a small proportion of the materials used, and thus serve as a guide. For the major portion of the operations, good inspection is the key to achieving a good embankment.
D. Preparation of embankment foundation	* Indicate that all unsuitable material should be removed from the embankment foundation area.
1. Compaction	* The ground surface should be rolled to provide a firm surface for compacting the first layer of fill.
2. Leaving topsoil in place	* Mention that the 1962 specifications of New York State allow leaving topsoil in place under embankments more than 6 feet high. The topsoil layer will consolidate rapidly under the embankment loads, and will have sufficient strength.
E. Dumping and spreading	* State that the soil must be spread in 8-inch lifts before compaction.
1. Scraper units	* Scraper units can adjust dumping to spread the soil out.
2. Trucks	* Mention that dumping should be planned so that bulldozers and scrapers can spread the material with a minimum of effort.

22427

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. End dumping	* No embankment may be placed in its final position by end dumping, except underwater fill.
F. Compaction	* State that the essential control of compaction equipment stated in the specifications should be enforced.
1. Uniformity of compaction	* Explain that the intent of the compaction procedures is to obtain adequate and uniform compaction throughout the embankment. There is an age-old argument that construction equipment working on the embankment will provide compaction. The truth is they do not provide uniform compaction. Equipment operators inevitably will follow the tracks of preceding equipment.
2. Equipment and procedures	1. Equipment must be appropriate for type of soil. 2. There must be sufficient load or ballast for compaction. 3. A minimum of six passes should be made over the entire surface of lift. 4. The minimum number of passes must be determined after appropriate field tests to evaluate the effectiveness of the rolling equipment. 5. The rate of fill placement should not exceed the capacity of the compaction equipment.
3. Behavior of soil under construction equipment	* State that this discussion will explain the observed behavior of soils under moving loads from compaction and hauling equipment. * Illustrate with the picture of a soil mass consisting of soil particles and voids filled with water and air. Refer to Figure 7-1 in Lesson 7.
a. Mechanics of soil action under wheel load	1. When a sand and gravel soil is under a wheel load, the soil tends to compress into a smaller volume. The soil is permeable

22428

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

enough so that the water and air flow out of the voids under the wheel load to areas of lower water pressure.

2. When wheel loads are applied to soils containing silt and clay, the water and air cannot escape because of the low permeability. The soil cannot densify until water and air are expelled. Therefore, part of the wheel load is carried by air and water, resulting in a pore pressure. This pore pressure travels in all directions away from the wheel. (Fig. 8-9)

FIGURE 8-9
SOIL DEFORMATION UNDER WHEEL LOADS

b. Spongy or weaving fills

1. The pore pressures adjacent to the wheel are great enough to force the soil up in a traveling wave. As the wheel passes on, the soil springs back into place.

22429

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	This condition is called a weaving, or spongy, fill.
	2. If this weaving occurs during rolling, lighter rolling equipment should be used.
	3. Usually weaving occurs under hauling equipment where the wheel loads may be heavier than the compaction equipment loads.
	4. Depressions in the full surface should be graded and compacted to a smooth surface before placing the next layer of embankment, in order to obtain uniform compaction.
c. Time effects	* Residual pore pressures are left in the soil mass after the wheel load has passed. These pressures will dissipate with time, and the soil will regain its original strength. Repeated traffic loads will continue to increase the residual pore pressures after each load application, with a resultant continuous decrease in strength between soil particles. This increases the weaving action until complete shear failure, or rutting, occurs.
d. Conclusions	1. A fill that is spongy, or weaving, under heavy hauling equipment loads is not unsuitable, providing required densities have been obtained. In the upper portion of the fill, within 4 feet of final grade, other considerations apply, and these will be discussed in a later section
	2. Tracking, or repeated traffic loads, should be avoided, as weaving will become worse.
	3. The fill will regain its original strength with time.

22430

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	4. Rutting indicates a shear failure of the fill, and it should be graded and recompacted. Rutting also ruins surface drainage and makes it impossible to place lifts in uniform layers. The 1962 specifications of New York State require the contractor to repair and recompact embankments damaged by hauling equipment.
4. Compaction equipment loads	* Mention that it is possible to have compaction equipment loads which are too great to properly compact the soil.
a. Pneumatic-tired compactors	* When loaded too heavily, the rubber-tired compactor will shear and rut the soil under the wheels. Ballast load should be decreased.
b. Sheepsfoot roller	* When loaded too heavily, the sheepsfoot roller weight will ride on the drum instead of the feet. Ballast should be decreased until the tamping feet will "walk out" of the soil after successive passes.
G. Drainage	* Mention that if water is allowed to stand on the fill surface seepage into the fill will soften and decrease the strength of the compacted material.
1. Fill surface	* The fill surface during and after construction should be crowned and rolled to insure satisfactory drainage at all times.
2. Ditches	* Sufficient ditches are required for drainage.
H. Estimating optimum moisture content	* State that an experienced inspector can estimate if a soil is near the optimum moisture content from its appearance.
1. Nonplastic soils	* State that for sands, gravels, and nonplastic silts, the soil will be near the optimum moisture content when it can be compressed into a firm cast by hand.

22431

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Plastic soils	* For plastic soils containing clay, the optimum moisture content (OMC) is near the plastic limit. If the soil is rolled into a thread, it should begin to crack and fall apart when the thread is 1/8 inch in diameter.
I. Drying wet soils	* State that frequently in cut excavations, soils will be encountered with natural moisture contents above the optimum. * These soils will require drying before compaction, and may be dried in the cut or on the fill.
1. Drying in cut	* Explain that drying is accomplished by exposing the soil to aeration and sunlight.
a. Manipulation	* Drying can be hastened by manipulating the soil with cultivators, disc harrows, or rotary speed mixers used with the hoods raised. The key is to expose the maximum surface area of soil to air and sun.
b. Exposure of large cut areas	* The contractor should plan operations so as to open up large areas of the wet cuts and gain the maximum advantage from drying.
c. Information from borings	* The moisture conditions and type of soil in a cut can be estimated from the project explorations. In clay cuts, moisture content profiles are often prepared from the drill hole samples.
2. Drying on fill	* Fill material may be spread on the embankment and dried prior to compaction. * Changes in weather may hold up all filling operations as fill becomes wetter. * Drainage of the fill surface to protect lower layers from wetting by rain is difficult.

22432

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Types of problem soils	* Soils containing large amounts of silt or clay are usually the wetter soils. * Clay soils are the most difficult to dry. * Brown, weathered clay soils from above the water table are easier to dry than gray clays from below the water table. It is difficult to compact some clays at moisture contents higher than optimum because of the low strength characteristics of these soils.
J. Compaction of subgrade foundation	* Define subgrade foundation as an area with a top width equal to the width of pavement plus 1 foot on each side, the sides sloping down and out at a 45° angle, and with the bottom 4 feet below the top outer edge of the pavement. (Ref. H, p. 198)
1. Traffic loads	* This zone of the embankment will support the traffic wheel loads. Review Figure 6-13.
2. Climatic effects	* This zone of the embankment will also be affected by freezing and thawing. Plate bearing tests indicate that in the spring immediately after thawing, the subgrade soil may have only 20 percent of the strength present in the fall. The strength returns slowly over the summer months. (Fig. 8-10)
3. Compaction requirements	* Mention that it is important for this portion of the embankment to be compacted as well as possible. Specifications require a minimum dry density of 95 percent of the maximum density and, for granular soils (less than 20 percent passing No. 200 sieve) a minimum dry density of 100 percent of the maximum density. These requirements are higher than for the lower embankment.

22433

Course Outline:

The following table provides a listing of course units along with time estimates for each unit. Both sequence and estimates can be varied to meet student needs. Units are presented concurrently as students achieve objectives that prepare them to move ahead.

Course Unit		Title	Hours	Code
Unit	I	Occupational Orientation	5- 7	-01
Unit	II	Fundamentals of Typing	70- 85	-02
Unit	III	Production Typing	60- 80	-07
Unit	IV	Office Equipment	20- 30	-03
Unit	V	Communications	15- 20	-04
Unit	VI	Financial Activities	8- 10	-08
Unit	VII	Record Management	15- 20	-09
Unit	VIII	Sources of Information	3- 5	-05
		Total	196-257	

2212

CONTENT OUTLINE TEACHING POINTS AND TECHNIQUES

FIGURE 8-10
SEASONAL VARIATION IN BEARING STRENGTH OF SUBGRADE

4. Proof rolling

* Proof rolling is performed on the top of the subgrade, which is the embankment or cut surface immediately below the lower granular subbase layer.

a. Procedure

* The entire subgrade surface is rolled with a 30- to 50-ton pneumatic-tired roller, in three or four passes.

* In areas where weaving or rutting occurs, the soft material is replaced with suitable granular material and recompacted.

22434

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* In areas where compression occurs, additional suitable material is added and compacted to bring the surface of the subgrade to proper elevation.
b. Purpose	* The purpose of proof rolling is to provide a uniform support for the granular subbase and pavement.
	* Weaving and rutting materials are removed because they tend to mix with and contaminate the gravel in the granular subbase layer when critical climatic conditions are combined with repeated traffic loads.

ASSIGNMENT

1. Read Chapter 14 of Ref. A: "Soil Compaction and Stabilization."

22435

Lesson 9 - Compaction Control Test - Subbase Courses - Stabilized Soils

OBJECTIVE

To explain the details and use of the compaction control test and the function of subbase course of granular materials and stabilized soils in highway construction

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Compaction Control Test	* State that field density tests are made to determine the degree of compaction obtained to insure conformance with the specifications.
	* Note: The following section is an outline of the compaction control test. Further details may be found in Ref. J.
A. Field density test	* The location of the field density test should be carefully chosen to:
	1. Represent the average soil type and average compaction effort for a lift of embankment
	2. Check specific areas where compaction is doubtful or where

22436

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	a change in fill material has taken place 3. Check areas where previous values of density have been low and conditions have been improved by additional rolling or other means
1. Test procedure	* Note that the steps of tests are outlined. It is suggested that the class be shown the density test equipment. If the class has not conducted this test in the field, the instructor may desire to use the detailed procedures in Ref. J. 1. A hole is dug in the fill 6 inches in diameter and 6 inches deep. 2. The volume of the hole is determined by the sand cone apparatus. 3. The material taken from the hole is weighed and then dried to determine the moisture content. 4. From the volume, wet weight, and dry weight values, it is possible to compute the wet density, dry density, and moisture content.
B. Dry density from standard compaction test	* Explain that the standard compaction test is conducted in the field laboratory. 1. A portion of the wet sample is compacted in layers in a standard compaction mold as described under laboratory compaction tests in the prior lesson. 2. The moisture content and dry density are determined.
C. Compaction control curves	* Mention that compaction control curves are prepared for each project. A set of curves is made for each type of soil that will be encountered on the project.

22437

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

FIGURE 9-2
PUMPING OF PAVEMENT JOINTS

* Continued pumping action results in a void under the pavement, and a failure of the concrete slab occurs adjacent to the joint.

2. Critical soils

* Critical soils for pumping are gravels that contain large amounts of fine-grain soil. Shale-type gravels fall into this category after the gravel fragments break down to silt and clay sizes.

III. Stabilized Soils

* Stabilization of soils consists of adding a chemical to the soil to make the effect of mechanical stabilization more lasting.

* State that adequately compacted soils are capable of carrying the heaviest traffic loads.

* Without additional treatment, soils will abrade rapidly under traffic; and they will soften as a result of wetting, drying, freezing, and thawing. (Ref A, p. 412)

A. Use

* State that stabilization methods are used for the following purposes:

1. Low-cost road surfaces
2. Roadway shoulders
3. Subgrades and base courses
4. Parking areas

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Soil cement	* State that cement may be mixed with a soil to form a low-strength concrete. * Cement will not mix readily with soils containing clay and will not set up properly with soils containing organic materials.
1. Procedure	* Describe steps of the treatment: (Ref. H, Item 59Y, p. 428) 1. Preparation of soil grading and shaping 2. Distribution (The amount of cement is about 5 to 16 percent by weight of the soil. The exact amount will vary with the type of soil. The fine-grain soils will require the most cement.) 3. Mixing, to be done when soil is dry to a depth of 6 to 8 inches (Special equipment is manufactured for this work.) 4. Addition of water 5. Compaction, which may be done with sheepsfoot, pneumatic-tired, or smooth-wheel roller 6. Curing period, a maximum of five days 7. Seal coat and wear coat (stone chips) to provide protection against wearing by traffic
C. Bituminous stabilization	* State that the strength of soils can be increased by coating each particle with bitumen. Usually a graded gravel is used for the soil.
1. Procedure	* Describe steps of the treatment: (Ref. H, Item 59W, p. 424) 1. Placement of the gravel layer 2. Applying bitumen (A medium-curing cutback asphalt or emulsified asphalt is used. Application is with a pressure spray bar, followed by a power-driven rotary-type mixing machine. Several passes may be required.)

22447

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	3. Curing (A period of seven days is required before rolling.) 4. Compaction (Done with a pneumatic-tired roller. The final rolling is done with a smooth-wheel roller.) 5. Seal coat and wear coat (Stone chips are applied.)
2. Plant mix	* The gravel may also be mixed with the bitumen in a plant before placing.
D. Calcium chloride stabilization	* State that calcium chloride stabilization is based on the deliquescent hygroscopic properties of the chemical. Deliquescence is the ability to absorb moisture from the air and to change vapor moisture to liquid. The hygroscopic property is the ability to absorb and retain moisture without necessarily becoming liquid. The two properties keep the soil moist during the dry seasons and prevent loss of shear strength from drying. This process also eliminates dust. * The stabilization effects are questionable during wet seasons when the soil loses strength because of too much water. * Seepage will dissolve calcium chloride and remove it from the soil. *(Ref. H, Item 59C, p. 421)*
E. Sodium chloride stabilization	* Sodium chloride achieves about the same results as calcium chloride through electrolytic and crystalline properties, which retain water in the soil mass.
F. Lime stabilization	* Lime is used to stabilize plastic clay soils principally in the subgrade. Lime reduces the plasticity of some clays. An increase in shear strength results.

ASSIGNMENT

1. Study Refs. G, J, and K, if they are available for class distribution.

22448

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Explain that the principle of a compaction control curve is based on the following facts:
1. Variation in soil properties	* State that the moisture-density characteristics of a soil will vary mostly with gradation, shape of particle, and plasticity. In a soil deposit, all of these properties vary in some degree.
2. Effect on moisture-density curves	* If moisture-density curves are prepared for many samples from a soil deposit that appears uniform, the curves will not plot in the same area on the graph.
3. Properties	* Illustrate with sketch the family of curves and their identical properties. (Fig. 9-1) 1. The shape of the curves will be nearly identical. 2. The position of the curves will be offset to the left, as the optimum moisture content decreases.
4. Plotting standard compaction point	* Mention that the moisture-density point from the laboratory test should fall anywhere in the family of curves.
5. Optimum moisture content of laboratory sample	* Explain and illustrate that a theoretical moisture-density curve may be drawn through the point following the general curvature and parallel to the straight portions of the adjacent control curves. (Fig. 9-1) * Show how the optimum moisture content and maximum dry density for the laboratory sample are determined.
D. Determination of percent of maximum density	* Explain that the dry density of a field sample, divided by maximum dry density from the compaction control test, times 100, gives the percent of compaction.

FIGURE 9-1
TYPICAL COMPACTION CONTROL CURVE

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Field densities above 100 percent	* Point out that field densities greater than 100 percent often are obtained. The reason is that the compaction energy of the compaction equipment is greater than that of the compaction effort of the standard density test.
E. Nuclear test methods	* Mention that in the past 10 years some agencies have adopted nuclear test methods for conducting the field density test. Nuclear tests can be performed in about one-fifth the time for the regular density test described previously. (See Ref. G, p. 124.)
1. Density test	* Describe the features of the test for density: 1. A probe with a radioactive source is inserted in the ground through a driven tube. Some types are placed on the ground surface and testing is done without driving a tube. 2. Gamma neutrons are sent out into the soil from the radioactive source. (Radium, cobalt 60, or cesium 137) 3. The intensity of neutrons bouncing back is measured. Density of soil is related to intensity.
2. Moisture content	* Mention these points in the test for moisture content: 1. A probe with a radioactive source of radium-beryllium is placed in the ground. 2. "Fast" neutrons colliding with hydrogen atoms in water are slowed down and return to the source as "slow" neutrons. 3. The intensity of "slow" neutrons determines the moisture content.

UNIT I (14.0901-01)

OCCUPATIONAL ORIENTATION

Performance Objectives:

Upon completion of this unit the student will be able to describe orally the general purpose and organization of business. She will be able, as determined by instructor observations, to demonstrate good interpersonal relations with other class members and good organization of a work station.

The student will be able to demonstrate in a role playing, or other simulated situation, the proper dress and grooming for an office worker and correct techniques and good manners. She will be able to score 80% on an objective test covering the responsibilities of a clerk-typist.

Unit Outline:

A. Review of Modern Business Enterprise

1. Methods of organization
2. Purposes of business

B. Types of Offices and Opportunities for Office Workers

C. What Business Expects of Office Workers

1. General expectations
2. Appropriate attire
3. Posture and figure control
4. Complection and health
5. Personal hygiene

D. Office Techniques of Etiquette

1. Basic good manners
2. Application of social graces to office situations
3. Some special problems that occur

E. Interpersonal Relations

1. Role of motive and emotion
2. The office worker's role in business-human relations activities

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Advantages	* Mention these advantages of nuclear testing: 1. Speed of operation 2. No disturbances of soil structure
4. Disadvantages	* Mention these disadvantages of nuclear tests: 1. High initial cost 2. Uncertain accuracy 3. Difficulty of choosing the correct compaction control curve (In the previous section it was shown that there is an individual compaction curve for each sample, and that for any soil deposit there is a family of curves. Without knowing the compaction curve for the sample tested in the field, it is difficult to choose the correct maximum density as determined by the standard compaction test.)
5. Use in New York State	* State that nuclear units have been used in the New York State Department of Public Works on an experimental and research basis.
II. Subbase Courses	* Define the subbase course as a layer of selected granular soil supporting the pavement.
A. Functions of subbase course	* Describe the purposes of the subbase course layer: 1. To provide uniform support to the pavement 2. To distribute the pavement and traffic loads to the underlying subgrade soil 3. To decrease frost heaving under the pavement 4. To provide drainage for water infiltrating through the pavement or from below. The effectiveness of the drainage will vary with the gradation of the

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	gravel. Most subbase gravels are quite impervious when compacted.
B. Requirements for soil properties	* Mention that, for the performance of the above functions, the following soil properties are required:
1. Strength	* Explain that soil must have internal strength to support the superimposed loads.
a. Particle sizes	* Strength is obtained by using a material composed mostly of gravel and sand-sized particles.
b. Gradation	* A well-graded sand and gravel will develop high densities and high interlock strength.
c. Limitation of fines	* Strength must be permanent and not subject to change due to variations in water conditions. This is assured by limiting the amount of silt and clay-sized particles in the material.
2. Frost heaving	* State that the subbase course is in the zone of frost penetration. A subbase material susceptible to frost heaving and subsequent loss of strength on thawing would result in pavement failures.
a. Limitation on amount of fines	* Frost heaving may be controlled by limiting the amount of silt and clay-sized particles in the material. Tests and experience indicate that in a well-graded sand and gravel subbase course, frost heaving is eliminated when not more than 10 percent of the sample passes the No. 200 sieve and the plasticity index test of the finer soils is not greater than 3.
b. Density	* The material should be dense in order to reduce the tendency for water migration with subsequent softening and loss of strength.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Drainage	* Explain that drainage is desirable to remove water leaking through the pavement or rising from subgrade. If the subgrade is impervious, this drainage will be lateral. * For well-graded sands and gravels the rate of drainage may be relatively slow due to the high density of the soil.
4. Soundness of gravel	* State that the gravel-sized material must be sound stone that will not break down into smaller particles under the effects of freezing and thawing. 1. Such breaking down results in reduction of strength. 2. Gravel derived from shale rock may behave in this manner.
C. Subbase course requirements in NYSDPW	* State that the subbase course material may be gravel, slag, or broken stone, provided it meets the specifications. (Ref. K) The term "base course" is used for crushed-stone bases for flexible pavements.
1. Subbase course materials	* State that there are two types of subbase course materials.
a. Select granular material	* Describe the test requirements for select materials. (Ref. H, p. 275) 1. Gradation 2. Plasticity 3. Soundness or quality
b. Granular material	* Describe the test requirements for granular material. 1. Gradation 2. Plasticity 3. Soundness
2. Magnesium sulphate soundness test	* Explain that the soundness test is a duplication of the effects of freezing and thawing on gravels.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	1. The sample is sieved before testing. 2. The sample is run through four cycles of soaking and drying in a magnesium sulphate solution. 3. Upon drying, the salt crystallizes and expands. 4. If there are cracks in the stone, the pressure of crystallization breaks the stone apart at the cracks. This is similar to freezing action. 5. The sample is sieved after the test. 6. The decrease in weight retained on all the sieves indicates the amount of particle breakdown that has occurred. 7. If the total sieve weight loss is greater than 20 percent, the gravel is unsuitable for select granular material. If the sieve loss is greater than 30 percent, then the material is unsuitable for granular material.
D. Subbase course design	* Mention that the usual thickness of the subbase course is 12 inches. Thicknesses up to 36 inches are used occasionally where the subgrade soil in cuts has extremely low strength.
1. Subbase course--select granular material	* State that the higher-quality gravel is used next to the pavement in all designs.
2. Subbase course--granular material	* In some shale areas, local deposits of sound gravel are difficult to find and expensive. * A two-course subbase course is used with 6 inches of select granular material on top, over 6 inches of granular.
E. Construction of subbase course	* Explain that the subbase course should be properly compacted to attain adequate strength.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Mention that construction traffic on the subbase course will mix fine-grained soils with the gravel. This adversely affects the strength, frost-heaving properties, and drainage properties of the layer.
	* See Ref. K for a detailed discussion of construction practice.
F. Sources of foundation course gravel	* State that most subbase course gravel is obtained from sand and gravel outwash deposits in the vicinity of the project.
1. Gravel pits	* Emphasize the importance of the following: 1. Not mixing unsuitable overburden material with subbase course gravel 2. Conducting excavation operations so as to thoroughly mix sand layers and gravel layers, since select granular material requires stockpiling and sampling
2. Processed subbase course material	* State that in some parts of New York State natural gravel deposits are becoming depleted.
a. Crushing	* Some contractors have crushed and processed rock excavation or oversized gravel. Emphasis of construction control is placed on mixing and stockpiling in order to reduce segregation.
G. Pumping	* Define pumping as a condition that develops at the joints of concrete pavements. (Fig. 9-2)
1. Mechanics	* When water collects below the pavement, heavy wheel loads will cause the water to be ejected with force at the joints.
	* Fine-grain soils in the subbase will be carried out with the water.

Lesson 10 - Influence of Soil Conditions on Highway Design and Construction

REFERENCES CITED IN THIS LESSON

New York State, Department of Public Works, Division of Construction. Public works specifications of January 2, 1962. Albany, New York. The Division. 1962. (Referred to in this unit by symbol "H")

OBJECTIVES

1. To describe soil problems that are often encountered in design and construction
2. To describe the soil behavior in these problems and to discuss possible solutions

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Embankment Foundation Problems	* State that embankment foundation problems involve the support of the embankment by the natural soil. Refer to the discussion of stability and consolidation properties of soils and design solutions in Lesson 6.
A. Foundation stability and settlement	* Mention that field investigations are made under the supervision of the district soils engineer. Testing and design analyses are conducted by the Bureau of Soil Mechanics. Close coordination is required between the designer and the other units, in order to determine the most economical solution. Berms are often required to provide stability for a high embankment on soft silt or clay.
1. Berm design	* State that a design report including typical sections is submitted to the District from the Bureau of Soil Mechanics.
2. Berm construction	* Mention that berms should be made concurrently with embankment.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* The embankment should never be completed prior to berm construction, since the critical time for shear failures is at the end of embankment work.
a. Inspection	* Recommend that fill construction be watched in critical stability areas for any long cracks or subsidence that may develop on the embankment surface, or upheaval of the ground surface outside the toe of the slope. Observations of this type should be reported immediately to the district soils engineer.
3. Surcharge construction	* Remind the class that surcharges are used to decrease post-construction foundation settlements. Surcharges and waiting periods are often used in the vicinity of bridge abutments to eliminate the need for pile foundations.
a. Inspection	* State that all surcharge material should be properly compacted and the final surface rolled and sealed for drainage.
	* Failure to follow the above procedures may result in a very wet subgrade when the surcharge is removed.
4. Construction control devices	* Construction control devices are included in the design to determine the safe rate of fill replacement and the rate of foundation consolidation for major stability treatment problems.
a. Consolidation and strength relations	* Remind the class how, in Lesson 6, the study of soil consolidation indicated that embankment load was carried first by the pore water in the soil, and then transferred to the soil particles as consolidation progressed. Soil strength also increased with consolidation.
b. Pore pressure	* In slow-draining soils, a portion of the embankment load is carried by pore water and is called the pore pressure. Pore pressure decreases with consolidation.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
c. Piezometer	* Define a piezometer (pronounced pee-zom-eter) as a device for measuring the pore pressures in soil masses. (Fig. 10-1)

FIGURE 10-1
PIEZOMETER INSTALLATION

(1) Description	* Describe a piezometer as a porous carborundum tube placed in the ground by means of a drill hole and connected by air-tight tubing to a standpipe extending above the ground surface.
(2) Principle	* The height of water (H) in the standpipe above the ground water table indicates the pressure of the pore water in the ground at the porous tip, in pounds per square inch. Standpipes are not practical on most highway projects, and Bourdon pressure gauges are used instead. $\frac{H(62.4)}{144}$ = pore pressure (in p.s.i.)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* It is possible to determine from the pore pressure reading the percentage of consolidation of the foundation soil for a given fill height.
(3) Use of piezometer data	* By correlation with laboratory test data, it is possible to predict the available shear strength, the amount of settlement remaining, and the rate of settlement at any time during fill construction.
d. Settlement platforms	* Describe a settlement platform as a base 3 feet square placed on the ground surface with a pipe extension that is carried up through the fill. By taking elevations on the top of the pipe, it is possible to plot a time-settlement curve of the original ground surface.
(1) Use of data	* Correlation of settlement records with laboratory consolidation test data allows predictions of future time-settlement rates.
(2) Construction of platforms	* Mention that the standpipe must not be disturbed by construction operations. A white barrel is often placed over the pipe.
B. Excavation of unsuitable material	* State that peats and mucks usually consist of 90 percent water by volume and 10 percent organic material.
1. Strength and settlement characteristics	* Explain that these soils have low shear strength and are removed from the area of future embankments.
a. Shear strength properties	* Mention that an embankment 5 or 10 feet high may be constructed on a deep peat deposit, and sink out of sight overnight because of shear failure.
b. Consolidation properties	* Embankments may be built less than 5 feet high, but will settle 3 to 4 feet in a few years due to consolidation of the peat.
2. Appearance of swamp deposit	* Mention that the surface aspects of swamp deposits may vary in these ways:

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	1. Open water 2. High water table with swamp grasses and sedges on surface 3. Full-grown forest, usually with high water table 4. Normal ground surface with no indication of underlying organic deposit (This condition usually occurs on flood plains where silts and sands may have been deposited over swamp. Buried organic deposits are often discovered by "springy" action of the ground under construction equipment. It should be brought to the attention of a soils engineer.)
3. Excavation procedures	* State that excavation is usually done by dragline, sometimes by clamshell.
a. Depth of excavation	* Mention that the depth of excavation should be determined by field explorations before construction. Additional explorations or probes may be required during construction if depths vary from cross-sections.
b. Over-excavation	* Observe that it is possible to excavate too much of the unsuitable material. 1. Organic soils are often underlain by loose silts or fine sands. 2. These materials appear unsuitable when excavated through water. 3. These loose, temporarily unstable materials left in place will consolidate and stabilize rapidly under the backfill, and will make an adequate embankment foundation. 4. Large-quantity overruns in excavation and backfill can occur because of unnecessary removal of loose silts and sands. In

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	a large swamp these overruns can cost several hundred thousand dollars.
c. Controlling depth of excavation	* The dragline operator is the key man on any muck excavation project. Mention these methods of controlling depth of digging: 1. Excavating to firm bottom, which is practical when organic soil is underlain by firm or compact soil 2. Excavating to a soil change or color change (Usually organic soils are dark and underlying soils are lighter.) 3. Excavating to a design elevation (This is practical when borings show a uniform deposit and the first two methods cannot be used.) Note: Be careful of changing surface-water levels during excavation.
d. Excavation side slopes	* State that as long as organic material is underwater vertical-cut slopes may be used. Although the soil has low strength, stability also depends on weight of soils. Organic soils weigh 65 to 70 pounds per cubic foot above water level, and 5 to 8 pounds per cubic foot underwater (due to the buoyancy effect). If the water level is lowered in the excavation, instability of slopes may be expected, owing to the increased weight of the soil.
e. Measuring excavation quantities	* Mention that cross-sectioning, using a probe rod to determine bottom, can be used. Aluminum rowboats are included in specifications for large projects.
4. Disposal of unsuitable material	* Emphasize that unsuitable material should not be side-cast next to an open

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	excavation, since its weight will cause shear failures and unstable excavation slopes. * In using organic material to flatten slopes, remember that organic material will shrink to a volume of two-thirds or even half the original volume, upon drying.
5. Underwater backfill	* State that granular material or rock is used for underwater backfill, and is usually placed by end dumping. * Remark that granular material will settle out fast underwater, will consolidate rapidly, and will have adequate shear strength. * Assert that materials containing considerable amounts of silt and clay will settle out very slowly, will consolidate slowly, and if placed in large chunks will soften and weaken over a period of time. * A minimum 2-foot lift above the water surface is usually required to support construction equipment.
C. Displacement of unsuitable material	* State that for organic deposits greater than 30 feet in depth the displacement method is often used, since it is difficult to excavate deep organic soil deposits. Displacement involves removal of the mudwave that has been pushed up in front of the fill. * The key to a successful displacement job is to keep the rate at which the mudwave is removed the same as the rate at which the fill is placed. This insures complete displacement of the organic material and allows the fill to sink to firm bottom.
II. Soils Problems in Cuts	* State that the two principal problems in cuts are stability of slopes and stability of subgrade.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Cut slope stability	* Observe that two types of slope failure occur: deep-seated and shallow-surface.
1. Deep-seated failure	* Mention that deep-seated failure usually occurs in a clay soil. The underlying clay has insufficient shearing strength to support the slope, and a circular-arc shear failure occurs. (Fig. 10-2) If the clay has water-bearing silt layers, the seepage forces will also contribute to instability.

FIGURE 10-2
CIRCULAR ARC SLOPE FAILURE IN CUT

a. Solution	* A critical failure condition can be solved by flattening the slope to reduce the overturning moment. * In very critical cases, a bench may be placed in the slope.
b. Design	* Designs of this type are usually based on strength-testing of undisturbed Shelby tube samples and stability analysis.
2. Surface failures	* Explain that shallow-surface failure is the most common type, and may involve either an entire slope or local areas in the slope.
a. Failures caused by seepage	* State that the prime cause of slope failures is water seepage. This reduces the shear strength of the surface soils, causing them to slide or flow.

22456

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
b. Solution	* State that instability of slopes due to ground water seepage may be remedied by placing a 2-foot gravel blanket over the critical area. This blanket reduces the seepage forces, drains the water, and acts as a weight on the unstable soil.
c. Slope protection blanket	* The gravel blanket must have special gradation in order to: 1. Be permeable enough to carry the water and reduce the seepage force 2. Have sufficient fines to prevent underlying soil from washing in and clogging voids * A special item "Granular Fill, Slope Protection " is included in the New York State Department of Public Works specifications.
d. Field correction	* State that in some cases the critical seepage zone may be determined from explorations, and the slope protection blanket may be included in the design. * Assert that for most cases critical seepage areas cannot be determined by exploration, and such areas will have to be treated as they appear during excavation and construction. * State that soils most likely to be unstable are water-bearing silts and layered clays. These occur in delta deposits and silt-and-clay bottom sediments. Silts may also occur as pockets in till deposits.
e. Failures due to thawing of frozen soil	* Often after construction sheet failures occur as frozen soils thaw on the upper and lower surfaces of the soil mass. Layers of supersaturated soils exist at the surface of the frozen material, and large sheets of surface soil and grass may slide

F. Personal Attributes

1. Punctuality

2. Physical health

3. Integrity

4. Leadership

5. Attitudes

G. Personal Efficiency in Identifying Responsibility, Planning and Organizing Work and Work Station.

Supplemental Teaching Aids:

Excellent resource people for this unit are working secretaries, State Department of Vocational Education personnel, beauty school operators or department store buyers.

The best general resource book is the Arizona State Department of Vocational Education's Suggested Curriculum Guide in Vocational Office Procedures. A good resource for role playing is Case Problems: for Vocational Office Block Project. This is available from the Department of Vocational Education also. Other useful resource books are: You as a Secretary, Royal Typewriter Company. How to be a Super Secretary, Remington Rand, and Sheaffer's Handbook for Secretaries, W. A. Sheaffer Pen Co., Fort Madison, Iowa ($1).

Some very good films are applicable to this unit. For example: "Office Etiquette" (15 min.), Britannica Press, Chicago, Ill., "Office Teamwork" (12 min.), Britannica Press, and "Off to a Beautiful Start", Scott Paper Co., Philadelphia, Pa.

Training Time 5-7 hours

2214

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	down the slope. Areas where sheet failures may occur are practically impossible to anticipate in design or construction.
B. Stability of cut subgrades	* State that the problem soils in cut subgrades are soft plastic clays and nonplastic silts.
	* Mixtures of sand, gravel, silt, and clay glacial till having more than 40 percent silt or clay will also be problem soils, but to a lesser degree.
	* The trouble starts when construction traffic travels on the subgrade and gets bogged down in the soils. The worst problem is the difficulty of building a stable subbase course layer on top of the soft soil.
1. Clay soils	* Mention that in clay soils the wheel loads cause failure by rutting. Further wheel loads continue to remold the soil and decrease the shear strength.
a. Solution: undercutting Note: Items 3 and 2EC are described in the New York State Public Works Specifications.	* The problem may be solved by undercutting the subgrade and placing a layer of sand and gravel (Item 3 or 2EC) over the clay. For most clay conditions, a layer 1 foot thick will be sufficient. For extremely soft clay, a 2-foot layer is required. This layer is sometimes called a working platform.
b. Mechanics of the working platform	* State that the working platform serves to distribute the wheel loads and reduce the shearing stresses in the clay.
2. Silt soils	* State that in silt soils wheel loads applied suddenly are carried by the pore water. The water pressures in the voids force the soil particles apart, leaving little or no strength in the silt. A weaving condition soon progresses to rutting.

CONTENT OUTLINE

a. Solution: undercutting

b. Pumping

c. Working platf material

3. General comments

III. Earthwork Factors

TEACHING POINTS AND TECHNIQUES

* The problem may be solved in the same manner used for the clay soils. For silt soils a heavier working platform, usually 2 to 3 feet thick, is required.

* State that the mechanics of failure of the silt soil can place the pore water under considerable pressure. The water carries silt upward into the overlying gravel layer. This action is called pumping, and in extreme cases the silt will work through the gravel, forming silt cones like miniature volcanoes. The pumping action is the reason heavier working platforms are used on silts than on clays.

orm

* Mention that the working platform material should be well graded with small void spaces to prevent silt from pumping. A two-layer system with sand on the bottom and gravel on top is also practical.

* Explain that construction engineers often try to use broken rock as a working platform. After several wheel load applications, the silt pumps up around the pieces of rock, and the working platform disappears under the silt. In some cases a well-broken-up shale in fine pieces has provided an adequate working platform on silt.

* Mention that a working platform of granular material should be extended to intersect the slope of the ditch in order that it will drain properly during and after construction.

* State that an important calculation in the design of a highway project is to determine the volume of excavation and the volume of embankment. The answers determine whether the project will require borrow, be a balance job, or require wasting. This is important for preparation of the contract estimate.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Definition of factor	* The earthwork factor is a number used to modify the cut volume in order to determine the embankment volume that will be obtained. For example:
1. Example	* Assume that the natural dry density in a cut is 110 (pounds per cubic foot). Assume that the compacted dry density in the embankment is 125 p.c.f. Then 1 cubic yard of cut will yield 110/125 cubic yards of embankment. The factor may be expressed in two ways: 1. Cut volume X $\frac{110}{125}$ (or .88) = embankment volume 2. Cut volume ÷ $\frac{125}{110}$ (or 1.07) = embankment volume * The second of the above methods, dividing the cut volume by a factor, is the general practice and will be used in the following discussion.
B. Effect of soil type on earthwork factor	* State that the density of the natural soil will have a large influence on the earthwork factor.
1. Water-laid soils	* Water-laid and wind-deposited soils are relatively loose and should be expected to have a smaller volume when compacted. (Earthwork factor greater than 1.0)
2. Glacial tills	* Glacial tills were compacted under several thousand feet of ice; compaction equipment cannot improve on the work of nature to much extent. Shrinkage will be little if any.
C. Effect of rock on earthwork factor	* State that rock in nature is in its most compact position and, when blasted and broken into small pieces, may never be compacted to its original volume again.
1. Swell factor	* Rock excavation will make a larger volume in the embankment. This is called the swell factor.

AUDIO VISUALIZATION PROGRAM
(AVPROG) (AVPLAY)

Aims and Purposes

TEACHING PROGRAMS AND DEVELOPMENTS

1. Concept

a. Audio Lab (Program in audio) (Program in audio and video) (Program in adaptation of AV TV to a classroom setting)

b. Use of Audio Lab

c. Use of Audio Lab (Program in audio and video)

2. Audio laboratory in audio and video

3. Audio of use

4. Coaching

5. Audio-visual and a division of audio-visual

a. Teaching (Teaching audio-visual) (Teaching audio-visual)

b. Teaching (Teaching audio-visual) (Teaching audio-visual)

c. Support of audio-visual

d. Education (AVE) (AV) (AV) (AV

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
c. Mechanics	* As the culvert deflects vertically under the fill loads, it expands horizontally. The horizontal expansion builds up resisting pressures in the surrounding earth.
d. Removal of struts	* Struts should not be removed until the fill is completed to subgrade.
e. Deflections	* Deflections of 5 percent of diameter are normal. Deflections of 20 percent of diameter are dangerous, and the culvert will fail by reverse curvature at the top of pipe.
D. Imperfect trench	* State that the imperfect trench method is used to decrease the fill loads on the pipe.
1. Procedure	* The compacted embankment is constructed to a certain height above the pipe, and then a trench is excavated and backfilled with loose, compressible material. Baled hay is used in New York State.
2. Theory	* The material in the trench will consolidate more than the adjacent embankment soil. The embankment above the trench will tend to arch over the subsided trench fill, and the weight will be carried by the adjacent embankment soil. This reduces the load on the pipe.
3. Practice	* If the top of an imperfect trench is too close to the pavement elevation, settlements will show up in the pavement.
VI. Structure Excavations	* State that the stability of temporary excavations for structure foundations or pipes is important, since failures may involve loss of life.
A. Labor code	* Mention that the State Industrial Code requires sheeting and bracing for all excavations "where any employee in an excavation is exposed to the hazard

22469

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	of falling or sliding material from any bank or side more than 5 feet above his footing."
1. Stable slope	* Explain that a stable slope varies with the type of soil and water conditions.
B. Effect of depth on stability	* As the depth of excavation increases, the maximum stable slope decreases.
C. Cohesive soils	* Explain that the strength of clay soils is derived from cohesion. The safe allowable slope may be determined from a circular arc stability analysis if the cohesive strength is known.
D. Nonplastic soils	* Sands, gravels, and silts derive their permanent strength from intergranular friction. The maximum stable slope is 1 (vertical) to 1-1/2 (horizontal.)
1. Capillary strength	* Nonplastic soils gain temporary strength from capillary forces in the pore water. Capillary forces hold the soil particles together and give the soil a temporary cohesive strength. * Drying of sand or gravel soils removes the capillary water and capillary strength, and a delayed failure results. This is the cause of many fatal cave-ins. An additional hazard once the soil has dried out is that sudden saturation by rain will reduce the capillary strength and increase the weight of the soil. Such drying can occur in one hour or take many days.
E. Surcharge loading	* Piling excavated material alongside the top of a trench will make the excavation stability more critical.
VII. Earthwork Computations	* State that in design it is necessary to determine the volume of excavation and volume of fill to prepare cost estimates for a project.

22470

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
a. Example	* Assume the rock density in cut to be 150 p.c.f. Assume the compacted density in embankment to be 115 p.c.f. The factor may again be expressed in two ways: 1. Cut volume X $\frac{115}{150}$ = embankment volume 2. Cut volume ÷ $\frac{150}{115}$ = embankment volume
D. Other influences on earthwork factor	* Numerous other considerations influence the earthwork factor and add to the difficulties of estimating in design.
1. Depth of cut	* State that the surface soils are usually looser than the deeper soils. For light cuts the factor should be higher than for deep cuts.
2. Hauling	* Mention that spillage during hauling serves to increase the earthwork factor. For example, truck hauling will have more spillage than scraper hauling. The spillage will increase with the length of haul.
3. Combined soils and rock excavation	* State that if overburden and rock are excavated together, a large portion of the earth will end up in the voids of the rock. The factor should be modified for this condition. * In cases where there is only 2 to 4 feet of overburden upon rock, the volume of earth should be neglected in the quantities, as it is almost certain to disappear in the voids of the rock fill. This increases the earthwork factor.
4. Waste	* Some soil excavation may be wasted because it is too wet to be properly compacted. * Some rock excavation may be wasted because of oversize. * Waste increases earthwork factor.

22461

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	the explosives in the bottoms of the holes. This results in poor fragmentation of the upper rock, and secondary blasting may be required.
3. Presplitting	* Indicate that presplitting is a new procedure being used in New York State to prevent overbreak on rock cuts.
a. Principle	* The purpose of presplitting is to create a barrier along the cut face, so that the rock forming the cut slope will not be disturbed by blasting in the cut.
b. Procedure	* Prior to fragmentation, blasting holes are drilled on 3-foot centers along the cut slope. Light charges are detonated to fracture the rock in the plane between the drill holes. This procedure is very successful. Presplitting must extend at least 20 feet ahead of fragmentation blasting.
c. Stemming	* Mention that stemming is the term used for filling the voids in the drill hole between charges. No. 1A stone is specified. The purpose of stemming is to prevent explosive gases from entering cracks or joints in the rock. Such gases decrease the effectiveness of the blast and may shatter the rock behind the presplit line.
d. Other methods	* State that there are other methods of slope drilling but that they are more expensive than the method described.
(1) Line drilling	* Drill holes are made on 6-inch centers along the excavation line, prior to the fragmentation blast. These holes are not loaded. As a general rule, the spacing is twice the diameter of the drill holes.
(2) Slash blasting	* The center of the cut is blasted and excavated. The sides are then drilled and blasted with light loads to trim to shape.

22465

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
V. Culvert Pipe Construction	* Emphasize that the successful performance of culvert pipes depends upon the installation. The majority of culvert failures are due to poor construction and inspection practices.
A. Design	* State that design sheets are available, showing the strength of pipe required for various loading conditions.
B. Rigid pipe	* Mention that rigid pipe is that which depends upon its inherent strength in conjunction with proper bedding, to support the superimposed loads of backfill and traffic.
1. Types	* Rigid pipes are of plain and reinforced concrete, vitrified clay, asbestos cement, and cast iron.
2. Bedding	* State that proper bedding is necessary to distribute the load across the bottom of the pipe. The best means of achieving proper bedding is a template.
3. Backfilling	* Careful backfilling is required to protect the pipe from construction equipment loads and to eliminate settlement of the roadway.
a. Protection during construction	* A minimum of 2 feet of cover is required, with proper approach ramps, to protect pipe from construction traffic loads.
b. Material	* Gravel backfill is needed since it is the easiest material to compact to the required densities.
C. Flexible pipes	* State that flexible pipes are those which deflect within tolerable limits under load, and in so doing mobilize resisting pressures from the surrounding soil to support the imposed loads.
1. Theory of flexible pipes	* Explain that the strength of a flexible pipe is derived from ring compression. That is, compressive stresses must be equal all around if the pipe is to be stable. (Fig. 10-3)

b. Powder factor

c. Blast holes

d. Sequence of bla

e. Nonuniform load

TEACHING POINTS AND TECHNIQUES

* A 5-fo setback should be provided at the interface between the top of the rock slope and earth cut slope.

* Some weathered rock and soft shales may be loosened and broken up by heavy ripping teeth dragged by a bulldozer. Most rock, however, requires blasting to reduce it to sizes that can be loaded and hauled.

ting

* State that the two types of explosive used are dynamite and "anfo" (a mixture of ammonium nitrate and fuel oil).

* Define powder factor, a term used in blasting: the number of pounds of dynamite used to blast one cubic yard of rock. It varies from 1/2 to 2 pounds in highway construction, depending on the type and condition of rock.

* Explain that drill holes 3 inches in diameter are bored with pneumatic drills,for placing explosives. Usual spacing is 6 by 8 feet, or 8 by 8 feet, on centers. This is the most expensive operation in blasting.

asting * Explain that contractors try to obtain the maximum fragmentation for ease in excavation and placing in fill. The maximum size of rocks allowed in fill is 2 feet. The usual blasting round extends no more than 50 feet from the face of cut. The rounds are detonated with millisecond-delay caps, so that the blast proceeds back from the face of the cut. This allows more effective fragmentation and throws the rock outward into the cut where it can be more efficiently excavated. It is much more economical to heave rock in a horizontal direction than upward.

ding * In areas where fly rock is a problem, the contractor will often put most of

FUNDAMENTALS OF TYPING

Performance Objectives:

Upon completion of this unit the student will be able to type at a rate of 30 wpm/ecol.

Unit Outline:

A. Machine Fundamentals

1. Parts

2. Maintenance procedures

3. Manual and electric typewriters

4. Operation

B. Quality and Performance Standards

1. Speed and accuracy

2. Neatness

3. Language arts

C. Skill Development

1. Keyboard mastery

2. Manipulation of machine parts

3. Speed, accuracy, and erasing

D. Typing Applications

Supplemental Teaching Aids:

No suggestions will be made for this unit since free or inexpensive resources are not applicable.

Training Time 70-85 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
5. Rolling embankment foundation	* A slight lowering of the ground surface, due to the weight of hauling and compaction equipment, will increase the volume of embankment required. On low fills, the percent of volume increase may be considerable. * The same condition exists in borrow pits where construction equipment compacts and lowers the bottom of the pit. * These conditions increase the earthwork factor.
6. Stripping	* Removal of trees and surface growth tends to increase the earthwork factor.
E. Estimating earthwork factor	* From the foregoing, it should be obvious that a great deal of experience and judgment is required to choose the correct earthwork factor. * Probably the best method is to use factors guided by the actual quantities used in previous, completed projects under similar soil and construction conditions.
F. Summary of earthwork factors	* State that the following summary shows how earthwork factors may vary with different soils and rock.
1. Variation with soil type	1. Water-laid soils (sand and gravel, silt, clay) 1.15 2. Glacial till 1.05 3. Soft shale 0.85 4. Sandstone and limestone 0.75 5. Igneous rock 0.70
2. Variation with cut depth	* The next summary shows how factors may vary with depth of cut for water-laid soils. 1. Shallow cuts (less than 6 feet): 1.35 to 1.15, depending on vegetation 2. Moderate cuts (6 to 25 feet): 1.15 3. Deep cuts (more than 25 feet): 1.10

22462

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
IV. Rock Cuts	* State that the goal in designing rock cuts is to construct economically a safe cut slope that will require a minimum of maintenance and will eliminate the hazard of falling or fallen rock on the pavement surface.
A. Rock features to consider in design	* Mention that the factors affecting slope stability may be determined by a study of the rock cores and the structure of the rock outcrops in the problem area. The services of geologists are available for this work.
1. Structure	* The structure of the rock involves jointing, bedding, cleavage, and fracture.
2. Strength	* The strength of the rock is important in considering the allowable slope. The soundest rock will stand vertical.
3. Weathering	* The rock may be deeply weathered, more like a soil than rock. The rock may look sound when opened in construction but, from effects of freezing and thawing or wetting and drying, will spall and build talus slope. Some shales and sandstones behave in this manner.
4. Stratification	* In areas of thick-bedded shale and sandstone, the shale may weather more rapidly, undermining the sandstone.
B. Rock cut design	* State that adequate explorations are required to determine surface of rock and type of rock.
1. Design slope of rock	* Design slope may vary from vertical to 1-on-1, depending on rock features discussed above.
2. Setback to toe of rock slope	* The setback distance is to provide storage space for rock falls, and to keep falling rock from rolling onto the pavement. A 25-foot setback from pavement edge is considered the minimum distance if rock falls are expected to be a problem.

22463

Use coffee can with both ends removed

1. Unconfined can may be easily flattened by crushing between thumb and finger. No lateral support is available.

2. When can is confined in wooden "fill", can will sustain weight of man standing on it.

TEACHING POINTS AND TECHNIQUES

ration

* For daring instructors, this principle may be demonstrated with an egg. Carefully cup the egg in both hands and squeeze. As long as the pressures are equal all around, the egg will not break.

* The gauge of the pipe is determined from the seam strength required to resist the compressive force using a safety factor of 4.

* Standard design sheets are available for corrugated metal pipe.

* The standard corrugation is a depth of 2/3 of an inch and 2-1/2 inches between ridges. In 1965, a deeper corrugation of 1 by 3 inches was put on the market. This gives greater stiffness to the pipe and allows a lighter-gauge metal to be used. The saving in weight using the 1-by-3 corrugation is between 25 and 40 percent over the old type.

* State that proper bedding and careful compaction of the backfill are essential to a successful pipe installation. Gravel backfill is used, and a minimum cover for protection against construction is required. This is similar to the requirements for concrete pipe.

* Mention that some corrugated metal pipes are delivered with horizontal wire ties to hold a vertical elongation of about 5 percent of the pipe diameter.

* Structural plate pipes are made with timber strutting to elongate them by 5 percent.

* Vertical elongation is a type of pre-stressing that allows lighter-gauge metals to be used and/or greater heights of fill to be placed than with round pipe.

22468

MICROCOPY RESOLUTIO
NATIONAL BUREAU OF ST

ON TEST CHART
ANDARDS-1963-A

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Volumes from cross-sections	* The usual method of volume computation is from cross-sections prepared at 50-foot intervals and where major surface irregularities occur.
1. Average end area method	* Mention that the volume of cut or fill is obtained by computing the areas with a planimeter for each section. The volume of earthwork is determined by averaging the areas of two sections and multiplying by the distance between cross-sections. The volume of cut or fill is expressed in cubic yards.
2. Computer programs	* Quantities may also be determined by computers. Computers can be used, too, for plotting cross-sections. Input requires ground surface data, grade line, and typical section.
B. Earthwork factor	* Explain that the earthwork factor must be applied to the cut volume to estimate the embankment volume that may be obtained from the excavation.
1. Earth and rock excavation	* Indicate that quantities of earth and rock excavation must be computed separately since the earthwork factor will be different. Review previous discussion in this lesson on factors.
C. Determination of total earthwork volume	* First, determine the volume of embankment fill that can be built with excavation after earthwork factors are applied. Second, compare the quantity of available fill to the total fill volume to ascertain if additional borrow is required or if there will be excess material from cuts. (This is called waste excavation.)
D. Balance of cut and fill	* Explain that, in the past, designers tried to balance cut and fill for most economical design. With present-day design standards this becomes more difficult.
1. Economics	* Relate that a designer should use judgment in design to reduce the total

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	volume of earthwork for economic reasons. This will require study and adjustments of profile alignment and cross-sections, keeping the design standards in mind.
E. Earthwork factors influencing grade lines	* In preparing a highway design, the following factors should be considered. They may not be as important, however, as other design considerations, and adjustments may not always be possible.
1. Rock excavation	1. Explain that rock excavation is two or three times more costly than earth excavation. One should reduce rock excavation as much as possible.
2. Cuts in clay	2. If the clay is too wet to be used in embankments, reduce cuts in this material as much as possible, since excavation will have to be wasted.
3. Grade line in flood plain or swamp	3. Keep the grade line at least 4 feet above the high-water level for good performance of pavement.
4. Shallow cuts in wet silt or clay	4. Undercutting will be required for a working platform during construction. It may be more economical to raise the grade to provide 3- or 4-foot fill without undercutting.
F. Final earthwork summary	* Explain that all earthwork quantities are summarized for estimate purposes. These include unclassified excavation (earth, rock, and borrow), selected granular borrow, underdrain filter, subbase courses, and trench, culvert, and bridge excavation.

ASSIGNMENT

1. Study the class notes.

Lesson 11 - Highway Drainage

REFERENCES CITED IN THIS LESSON

Armco Drainage and Metal Products, Inc. Handbook of drainage and construction products. Middletown, Ohio. Armco Drainage and Metal Products, Inc. 1958. (Referred to in this unit by symbol "L")

Woods, K. B. Highway engineering handbook. New York. McGraw-Hill Book Co. 1960. (Referred to in this unit by symbol "B")

OBJECTIVES

1. To discuss the types of highway drainage problems
2. To study the principles of hydrology concerned with the frequency and intensity of runoff to be handled
3. To become acquainted with the procedures used in the hydraulic design of drainage facilities

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Introduction	* State that this lesson concerns methods of collecting, transporting, and disposing of surface water originating on or near the highway right-of-way, or flowing in streams crossing or bordering the right-of-way. It also covers control of subsurface drainage.
A. Economics	* Indicate that, on the average, 10 to 15 cents from each highway construction dollar is spent for culverts, bridges, and other drainage structures.
B. Legal responsibility for drainage	* Inform the class that highway agencies have legal responsibility for damage to private property resulting from changes they make in natural drainage patterns.
II. Types of Drainage Problems	* Mention that this section will summarize the different types of drainage problems and will discuss in detail those problems involved with soil properties.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Bridge waterway openings	* State that in most cases the height and length of a bridge depend on the amount of clear waterway opening required to accommodate the flood waters of the stream.
1. Design flood stage	* The structure is usually designed for a predicted maximum flood. * For example, a bridge may be designed for a 50-year flood interval. This would allow for a flood which can be expected, by the laws of probability, to occur on the average of once in 50 years.
2. Flood data	* Mention that the U. S. Geological Survey publishes flood data for many streams based on information obtained from stream gauging stations.
B. Highway culverts	* Define a culvert as any closed conduit used to conduct water under a roadway. * All conduits greater than 20 feet in total span are treated as bridges.
C. Municipal storm drainage	* Indicate that in urban areas runoff waters are carried through a system of storm sewers. * Drainage problems are increased by: 1. Impervious surfaces which create very high runoff 2. Too few natural water courses to handle the runoff
D. Roadway surface drainage	* Point out that roadways are built with crown or cross slopes, which provide lateral or oblique drainage flow to the sides of the pavement. The transverse slope is 1/4 inch per foot.
1. Disposal of drainage	* Usually the water flows across the road shoulder and down the slope to a natural drainage area, or to side ditches.

22474

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Erosion problems on fill slopes	* Mention that on embankments made of fine sand and silt roadway runoff will cause erosion gullies that work back under the shoulder. * Curbs may be placed at the edges of paved shoulders to control water. Inlets with ditches or pipes may be used to conduct water down the embankment side slope.
E. Ditches	* Point out that a highway cross-section normally includes ditches on each side of the roadway parallel to the centerline.
1. Purpose	* Ditches serve four purposes: 1. They intercept surface drainage from cut slopes and conduct water away from highway section. 2. They intercept subsurface drainage and conduct water away from highway. 3. They lower the water table below pavement, thus reducing the possibility of frost heaving. 4. They improve subsurface drainage of water that infiltrates pavement and shoulders.
2. Design	* Mention that ditches should be designed to accommodate the maximal flow of water. Sufficient waterway should be provided to prevent erosion of the roadway shoulder and undercutting the toe of the slope.
a. Dimensions	* The standard ditch section is 4 feet deep and 3 feet 8 inches wide, with a radial bottom.
3. Blasted rock trench	* Mention that blasted rock trenches are used in rock cuts where ground water is flowing through the joints or bedding planes of the rock. * The rock is blasted, creating a trench 3 feet deep and a minimum of 2 feet wide. The rock fragments are

No suggestions will be made for this unit since supplemental resources are not applicable.

Training Time 60-80 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	left in the trench. Care should be taken to have continuous blasting in order not to leave a dam of unbroken rock.
F. Cut slope drainage	* Proper control of drainage on a cut slope is difficult due to the high velocity of flow. This is a source of many maintenance problems.
1. Top-of-slope ditch	* State that the top-of-the-slope ditch is used for the erosion protection of cut slopes against runoff from the slopes above the cut. * Care should be taken in design to prevent erosion and subsequent spilling of water in concentrated quantity on the cut slopes. Paved gutters may be required for prevention of erosion on long, steep slopes.
a. Design	* Standard design for the top-of-a-slope ditch is a minimum 5-foot set-back from top of the slope, with existing vegetation remaining between the ditch and the top of slope. The minimum depth is 2 feet, and the width varies.
2. Slope benches with gutters	* State that slope benches are sometimes used to intercept water part way down the slope and to carry runoff along the bench to the end of cut, or to slope gutters or drain pipes at intervals.
a. Failure of slope benches	* Slope benches are unnecessary as drainage features, and usually perform unsatisfactorily for the following reasons: 1. The slope runoff resulting from precipitation on a slope will not cause erosion if the slope is covered with a growth of grass. Sufficient fertilizer, mulching, and proper choice of grass seed produce adequate grass cover on most cut slopes.

22476

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	2 or 3 feet per second. Good sod will erode when the velocity exceeds 4 to 6 feet per second.
b. Erosion	* Once the water overflows the gutter, it erodes the soil from under the gutter.
c. Damage	* The end result from loss of support and subsequent frost action is a gutter broken and twisted into many pieces.
d. Design	* Consideration should be given to designing a gutter with hydraulic properties adequate to carry the water, and with bedding adequate to resist frost heaving and cracking. The most difficult part of the design usually is channeling the water around the 90° turn from top-of-the-slope ditch down the slope gutter.
	* Corrugated metal pipe buried in the slope is one method of conducting water down the slope and avoiding erosion problems.
G. Subsurface drainage: underdrains	* State that subsurface drainage is an important factor in preserving a roadway surface.
1. Effects of water on subgrade	* Tests have indicated that during the spring thaw the bearing capacity of the roadway subgrade is suddenly reduced to about 25 percent of its autumnal strength; it slowly builds up again over a period of several months as the soil drains. (Refer to Figure 8-10 in Lesson 8.)
2. Importance of drainage	* The strength loss in the subgrade may be reduced if good drainage prevents water from accumulating in the subgrade.
	* The majority of pavement failures are caused by too much water and not enough drainage.

22478

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Purpose	* State that underdrains are pipe drains usually placed outside the pavement sections to accomplish one or more of the following results: 1. To drain the subbase course gravel 2. To drain the subgrade soil under the roadway 3. To intercept ground water coming from outside the roadway section
4. Mechanics	* Mention that damage to the pavement is due to loss of subsoil strength by the effects of water and frost. * Lowering the water table reduces the moisture in the soil and also lessens the tendency for water to accumulate by capillary rise. * Drains also help remove the water that infiltrates through the pavement and shoulder areas.
5. Type of underdrain	* State that the principal types of underdrain used are perforated corrugated metal, porous concrete, vitrified clay, asbestos cement, and bituminous fiber. * State the features of each as described in New York State Specifications. (Ref. H)
6. Design of underdrains	* The location of the underdrain depends on what type of drainage it is intended to accomplish. (Fig. 11-1)
a. Size	* For normal subdrainage 500 feet of 6-inch pipe may be used as an interceptor before any increase in diameter is needed.
b. Slope	* A minimum slope of 0.15 foot per 100 feet should be used.
c. Pipe outlets	* Free outlets are important. Many underdrains do not work because of plugged or damaged outlets.

22479

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Build outlets high enough so that they will not become plugged with silt or snow.
d. Depth of underdrain	* The bottom of a subdrain pipe should be deep enough in an impervious material to effect complete removal of the water. (Fig. 11-1a) In a pervious soil the water table is lowered to the bottom row of perforations. Space in the bottom of the pipe between the rows of perforations is sufficient to carry normal flow. (Fig. 11-1b)
7. Backfill material	* Mention that silting and plugging up is one of the main causes of failure in underdrains.
a. Requirements	* The underdrain filter material should be coarse enough to allow the water to drain into the openings of the underdrain (3/8- to 1/2-inch perforations or joint openings) without washing the fines out of the filter.
	* The material needs a gradation that will prevent the fine-grain material of the surrounding soil from washing into the filter and clogging the voids.
b. Materials used	* Up until 1962 a run-of-bank gravel was used. This material was so variable in gradation that it did not always meet the above requirements.
	* The 1962 Specifications (Item 2UF) require a better graded material which, if made of processed substance, will contain 50 percent concrete sand, 25 percent No. 1 stone, and 25 percent No. 2 stone. This higher-grade material will insure a satisfactory performance of the underdrain for a longer period of time.
	* Crushed stone is used by some agencies as a filter material. Tests indicate that this may clog up with fines from the surrounding soil over a period of time, with a serious loss in permeability.

22481

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

8. Installation

* Mention that underdrains may be placed in a trench or in a V-shaped excavation below the subbase gravel. This type of excavation may be made with a grader blade. (Fig. 11-2)

FIGURE 11-2
V-NOTCH UNDERDRAIN TRENCH
(Source: New York State Department of Public Works Standard Sheets)

a. Care

* Care should be taken to securely connect pipe joints. At least 4 inches of underdrain filter material should be placed below and around the sides of pipe.

b. Sealing surface

* Mention that underdrains below ditches should have a layer of impervious material above the filter material to prevent surface water from running in and silting up the granular backfill.

9. Construction considerations

* Explain that at the time underdrains are installed the soil may be dry and the underdrains may appear to be a waste of money. In the spring, however, when the soils are wet and the strength of soil is at a minimum, the drainage provided by the underdrain may save the pavement.

a. Transverse drainage

* Occasionally the grade line in a cut may intercept a water-bearing layer of soil. It is usually impossible to determine these areas from explorations.

22482

22480

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

The construction engineer should provide transverse underdrains in such areas. If the area is extensive, undercutting and backfilling with coarse granular material may be done across the seepage zone, and one or more transverse underdrains may be provided. Without treatment, this is a likely location for frost heaving and pavement failures. (Fig. 11-3)

FIGURE 11-3
HERRINGBONE SUBDRAINAGE LAYOUT
USED IN CUTS INTERSECTING WATERBEARING ZONES OF SOIL

H. Channel relocations

* State that relocation of natural water courses to keep them on one side of the roadway is often done to eliminate drainage structures.

1. Analysis

* A thorough analysis should be made of the hydraulic properties of the stream to determine the effect of relocation on stream flow and scour.

* Channel relocation should have the same type of hydraulic analysis as that given culverts and bridges.

2. Scour

* Mention that existing streams have stabilized in their channels over many years. Changing the channel may start

22483

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	unexpected erosion, scour, and undercutting of embankments and cut slopes.
a. Critical soils	* The most critical soils for scour and erosion are those made up predominantly of fine-grain silts and clays. Channel protection may be required, such as stone rip-rap.
I. Erosion protection	* Mention that the hydraulic design should be such as to prevent scour velocities if possible. When this is impractical, protection should be provided against scour.
1. Critical areas	* Scour or erosion should be prevented at culvert outlets; in all ditches, especially down-slope ditches where flow velocities are high; and on shoulders and slopes.
III. Hydrology	* Define hydrology as the science that deals with the occurrence and movement of water on and beneath the earth's surface. The application of hydrology to drainage design is in the estimating of the volume of water to be carried in the waterway or through a pipe.
A. Rainfall	* State that the application of hydrology important to drainage structures is the relation between rainfall and ultimate surface runoff.
	* The following three rainfall factors for design must be determined:
1. Intensity	1. The rate at which rain falls for a given period, usually expressed as inches per hour
2. Duration	2. The time during which rainfall prevails at that rate, usually expressed as minutes or hours
3. Frequency	3. The probable period of time within which combinations of intensity and duration repeat themselves, usually expressed in years

22484

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
b. Flow area (A)	* "A" is the channel flow area at high water.
c. Hydraulic radius (R)	* The hydraulic radius is defined as the area of flow divided by the wetted perimeter.
d. Wetted perimeter	* The wetted perimeter is the length of the boundary of the cross-section which is in contact with water. This is a definition from hydraulics.
e. Slope of channel (S)	* The slope of the channel is the drop in water surface per unit distance. This was determined from the high water marks. Units are feet per foot.
3. Sample problem	* Work out the sample problem on page 38 of Ref. M.
V. Culvert Design	
A. Design for fill loads	* Mention that after the required pipe size is determined the strength of pipe to carry the embankment loads should be determined.
1. Design charts	* Design sheets have been developed by the State Department of Public Works to show the required pipe to support various embankment heights.
a. Corrugated metal pipe	* The gauge thickness of metal required in corrugated pipe varies with the full height.
b. Reinforced concrete pipe	* Two types of concrete pipe are available: reinforced concrete and extra-strength reinforced concrete.
B. Culvert location and length	* Proper location of the culvert is important to provide adequate control of stream flow.
1. Alignment	* The stream should have a direct entrance and a direct exit. If a direct entrance or exit does not exist, it may be provided by:

UNIT IV (14.0901-03)

OFFICE EQUIPMENT

Performance Objectives:

Upon completion of this unit the student will be able to score at least 90% on an instructor established scale that considers both accuracy and time, in operation of adding machines and calculators. She will be able to demonstrate correct procedure and technique in operation of reproducing machines. The student will be able to tabulate 50 handwritten checks in one minute or less with no errors.

Unit Outline:

A. Machines

1. Ten-key Adding Machine
2. Full-key adding machine
3. Printing calculator
4. Rotary calculator
5. Bookkeeping machine

B. Reproducing Machines

1. Spirit
2. Mimeograph-mimeoscope
3. Copy machines
4. Other reproducing machines
5. Analysis of reproduction requirements and selection of method

C. Other Office Equipment

1. Paper cutter
2. Stapler
3. Collator
4. Lablemaker
5. Punching and binding
6. Tape recorder

2217

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	1. A channel change 2. A skewed alignment 3. A combination of 1 and 2
2. Prevention of stream changes	* Precautions should be taken to prevent the stream from changing its course near the ends of the culvert. Excessive ponding or washout of the roadway may result.
a. Protective steps	* Rip-rap, sod, paving, concrete headwalls, or metal end sections will help solve the above problem.
C. Culvert grade	* Explain that the ideal grade line produces neither silting nor excessive velocities and scour; it also provides the shortest length. (See Table of Scour Velocities, Ref. L, p. 210)
1. Minimum slope	* A minimum slope of 0.5 foot per 100 feet is needed to avoid sedimentation and erosion.
2. Average slope	* A slope of 1 to 2 percent is usually adequate.
3. Stream-bed grade	* Where possible, make the culvert grade coincide with the stream-bed grade.

ASSIGNMENT

1. Review the lesson lecture notes.

22489

5. In the laboratory, various amounts of clays are added to a sample of silt and sand. As the proportion of clay increases, which of the following best describes the behavior of the Atterberg Limits?

_____ a. The liquid limit increases, the plastic limit decreases, and the plasticity index decreases.
__X__ b. The liquid limit, plastic limit, and plasticity index all increase.
_____ c. The liquid limit, plastic limit, and plasticity index all decrease.
_____ d. The liquid limit, plastic limit, and plasticity index remain constant.

6. The No. 200 sieve is important in soil classification for which of the following reasons?

_____ a. All material retained on the sieve is classified as gravel.
_____ b. All material passing the No. 200 sieve is sand and silt.
__X__ c. The No. 200 sieve separates the coarse-grain sand and gravel from the fine-grain silt and clay.
_____ d. The No. 200 sieve separates the silt-size particles from the clay-size particles.

7. A proposed highway is to traverse an area that is hilly and wooded. The designer needs to know the depth of rock in cuts for preparing the cross-sections. Which of the following exploration methods would be the most practical to provide the design information?

_____ a. Drill holes with split-spoon drive samples
_____ b. Drill holes with core samples
_____ c. Auger holes
__X__ d. Seismic investigations
_____ e. A geologic survey mapping all rock outcrops

8. The results of the laboratory consolidation test are usually applied to which of the following design problems?

_____ a. Consolidation of embankment soils
_____ b. Settlement of soils due to vibration of traffic loads
_____ c. Determining earthwork shrinkage factors
__X__ d. Determining settlement of foundation soils caused by embankment loads
_____ e. Determining embankment stability

9. Granular foundation soils usually have sufficient strength to support all heights of embankments. The main reason for this is that:

_____ a. Granular soils build up extra capillary strength when loaded.
__X__ b. The granular soils consolidate rapidly as the fill is placed, with a corresponding increase in frictional shear strength in proportion to the load applied.

(continued)

22493

_____ c. Granular soils have a large shear strength, even before the load is applied, which is sufficient to support any load.

_____ d. The granular soils have unlimited shear strength, provided the side slope of fill makes an angle with the horizontal which is less than the friction angle (30°) of the granular soil.

10. Capillary forces play an important role in the strength of soils. Which of the following statements about capillarity is not true?

_____ a. The height of capillary rise in soils increases as the grain size decreases.

_____ b. Granular soils that develop capillary forces have greater strength than the same soil in a dry condition.

_____ c. Development of capillary forces in soils requires a partially saturated condition where the soil voids contain both air and water.

__X__ d. When a trench excavation is made in granular soils containing small amounts of fine-grained material, the capillary forces in the soil can provide sufficient shear strength to keep the sides of the trench permanently stable.

11. It is important to know the effect of compaction effort on the compaction characteristics of a soil. An increase in compactive effort on a given soil will do which of the following?

__X__ a. Decrease optimum moisture content and increase maximum density

_____ b. Increase optimum moisture content and increase maximum density

_____ c. Decrease optimum moisture content and decrease maximum density

_____ d. Increase optimum moisture content and decrease maximum density

_____ e. Have no effect on optimum moisture content or on maximum density

12. You are an engineer in charge of a project. A deep deposit of wet silt is encountered at subgrade elevation in a cut. It is impossible to get construction equipment through the cut. Which of the following solutions would you recommend for stabilizing the subgrade?

_____ a. Place a herringbone pattern of underdrains and put on subbase course gravel

_____ b. Increase depth of ditches

_____ c. Undercut until stable material is reached and backfill with gravel

_____ d. Undercut about 3 feet and backfill with large rock excavation if available

__X__ e. Undercut about 3 feet and backfill with well-graded gravel

22494

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Emphasize that frequency is based on the mathematical law of probability. For example, a 50-year rainfall intensity may occur twice in 1 year or once in 100 years. Analysis of past records, however, indicates it will occur, on the average, once every 50 years.
B. Runoff	* Mention that a portion of the precipitation is returned to the atmosphere by evaporation and transpiration through plant growth. Some water soaks into the ground, becoming ground water.
1. Surface runoff	* The remainder flows over the surface to small tributaries and major streams. This portion is called surface runoff.
2. Effect of ground cover	* The runoff varies with the ground cover. Runoff is much greater in an urban area, where there are many roofs and pavements, than in a forested area or dense grass.
C. Use of stream flow records	* Explain that the major streams in New York have continuous records of runoff, accumulated over many years. These streams are gauged by the U. S. Geological Survey and other agencies, and the records are published.
1. Lack of records for small streams	* Stream flow records for smaller streams, with less than 10 square miles of drainage area, are few. Other methods must be used to estimate design flow.
IV. Determining Flow for Culvert Design	* The major problems of stream-flow analysis are for culvert designs.
A. Definition of culvert	* Culverts are defined as structures with a span of 20 feet or less between abutments. This category includes all kinds of pipes as well.
B. Determining culvert size by inspection	* State that a practical method of deciding culvert size is to inspect an existing structure at the site. Observe the following steps:

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Channel condition	* Note the size, shape, and condition of the channel upstream and downstream.
2. Length of service	* Investigate the length of service of an existing culvert from records. Is the time of service long enough for 20- to 50-year runoff?
3. High water marks	* Maintenance personnel or local residents may have recollection of high water marks.
4. New culvert	* Estimate the adequacy of the existing culvert and base the size of new culvert on that estimate.
C. Determining culvert size by empirical formulas	* Empirical formulas have been used for many years to design culverts. They are "rule of thumb" procedures, and are gradually being replaced by more accurate and scientific methods.
1. Talbot Formula	* The area of the waterway may be determined directly from the formula: $a = C^4\sqrt{A^3}$
a. Required waterway opening (a)	* In the Talbot Formula, "a" is based on a flow of 10 feet per second.
b. Runoff coefficient (C): ratio of runoff to rainfall	* "C" varies from 1 to 1/5 according to the steepness of the land (Ref. L, p. 226) and the type of ground surface (Ref. B, 12-17K)
c. Drainage area (A)	* The drainage area, in acres, may be determined from USGS maps or air photos.
2. Rational method	* The system applied to watersheds of less than 1,000 acres is called the rational method: $Q = CiA$
a. Runoff (Q)	* Runoff is measured in cubic feet per second for total drainage.

22486

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
b. Intensity of rainfall (i)	* Intensity is measured in inches per hour. Charts have been prepared showing intensity versus duration. These are available in drainage manuals and from the U. S. Weather Bureau. Sketch the sample chart from Section 12, page 11, of Ref. B.
c. Time of concentration	* The intensity chosen for design should be equal to the time of concentration in minutes for water from the most remote corner of the watershed to reach the drain. Peak design flow cannot occur until this condition is satisfied. For watersheds of 1,000 acres, this time is 5 to 10 minutes, depending on the gradient and vegetation.
D. Analysis of the natural channel	* State that the volume of flow may be determined from an analysis of the natural channel approaching the culvert.
1. Field procedure	* The following information is obtained in the field: 1. A typical cross-section of the channel is determined. 2. The high water marks are determined to find the gradient of water surface at flood stage. A minimum channel length of 200 feet is required. 3. The material on channel sides and the bottom roughness are noted.
2. Manning Formula	* The Manning Formula for channel flow is used. This is based on hydraulics. $Q = \frac{1.486}{n} AR^{\frac{2}{3}} S^{\frac{1}{2}}$
a. Roughness factor (n)	* This factor depends on the roughness and type of sides and bottom. It varies from .125 for rough channel surfaces to .015 for smooth pipe surfaces. Tables are in hydraulic handbooks.

GLOSSARY OF SYMBOLS

a = area of waterway opening

A = area

C = cohesion (in Lesson 6)
runoff coefficient (in Lesson 11)

e = void ratio

G = specific gravity

h = head loss

H_c = capillary rise

H = thickness, height

i = hydraulic gradient (in Lesson 7)
rainfall intensity (in Lesson 11)

k = coefficent of permeability

L = length

LL = liquid limit

n = roughness factor

P = pressure

PI = plasticity index

PL = plastic limit

Q = quantity

R = radius (in general)
hydraulic radius (in Lesson 11)

S = degree of saturation (in Lesson 3)
shearing strength (in Lesson 6)
slope of channel (in Lesson 11)

(continued)

GLOSSARY OF SYMBOLS (continued)

SL = shrinkage limit

t = time

T_s = surface tension

v = velocity

V = volume

V_s = volume of soil

V_v = volume of voids

V_w = volume of water

w = moisture content

W = weight

W_s = weight of soil

W_w = weight of water

γ_d = dry unit weight

γ_s = weight of soil solids per unit volume

γ_t = total unit weight

γ_w = weight of water per unit volume

Φ = friction angle

Final Examination Part I -- Multiple Choice Questions

INSTRUCTIONS: Read all the following statements carefully, then place a checkmark in the space before the choice you consider to be the correct one.

1. The most common type of rock found in New York State is:

   X a. Sedimentary
   _____ b. Igneous
   _____ c. Metamorphic
   _____ d. Conglomerate

2. A location study is being made for a highway alignment in the southwestern plateau region of New York State. The line is in a broad valley which, in one area, is filled with irregular, hummocky hills for the entire width of the valley. Which of the following is the soil deposit most likely to be?

   _____ a. Outwash
   X b. Moraine
   _____ c. Delta
   _____ d. Eskers
   _____ e. Drumlins

3. The gradation of particle sizes has an important influence on the density of a soil mass. Which of the following types of gradation will usually give the greatest soil density in nature?

   X a. Well graded, including all grain sizes from coarse to fine
   _____ b. Soil containing round particles all of the same size
   _____ c. Soil containing flat particles all of the same size
   _____ d. Skip-graded soils containing large and small particles but no intermediate sizes

4. Which of the following is the correct definition of liquid limit?

   _____ a. The moisture content at which a clay soil starts to crumble when rolled into a thread 1/8 inch in diameter
   _____ b. The moisture content at which no additional water can be added to the soil
   X c. The moisture content at which a clay soil starts to exhibit shear strength
   _____ d. The moisture content required to fill the voids when the sample reaches its minimum volume

FOREWORD

This Teacher's Guide, *Highway Design and Estimating*, is one of a series in the Highway Technicians Program. This program was initiated by the New York State Department of Transportation (formerly the Department of Public Works) to help relieve the shortage of highway technicians. As a result of their initiative, the first editions of Units I through V were published, starting in 1961.

John L. DeLee, now Principal Civil Engineer in the Bureau of Highway Planning of the Department of Transportation (with the help of other personnel from the district offices of the Department), carried on the planning for the original series of nine units (or courses) in the Highway Technicians Program. Edward Umiker, now Associate Civil Engineer in the Buffalo District Office of the Department of Transportation, and Ralph Fimmano, Senior Civil Engineer in the Utica District Office, collaborated in developing the topical outlines for the nine units.

Early in 1967 Philip E. Hagerty, Assistant Administrative Deputy of the Department of Transportation, called for a renewed effort to complete all the units planned in the program and to update, as needed, those already published. As a result, several Department engineers were made available as consultants to the New York State Education Department to do the writing needed in completing and updating the whole series.

This Guide, *Highway Design and Estimating*, was written by Ralph Fimmano under the guidance of Berton P. Plummer, Associate in the Bureau of Occupational Extension and Industrial Services. Nelson S. Maurer, Associate in the Bureau of Continuing Education Curriculum Development, supervised the review and final preparation of the manuscript for publication.

To all the agencies and individuals mentioned above, this Bureau makes grateful acknowledgment for the responsibilities which they so faithfully fulfilled.

HERBERT BOTHAMLEY, *Chief*
Bureau of Continuing Education
Curriculum Development

WILLIAM E. YOUNG, *Director*
Curriculum Development Center

13. You are in charge of a highway design project on which there are high embankments to be built with fine sand and silt soils. You are concerned with erosion of the embankment slopes. Which of the following is the most practical method of preventing slope erosion from roadway runoff in order to reduce maintenance costs?

_____ a. Use topsoil, fertilizer, and grass seed on slopes
_____ b. Use sod strips on slopes
_____ c. Use asphalt curbs at edge of shoulder to confine water, and seeded gutters to carry water down the slope, at specified intervals
__X__ d. Use asphalt curbs at edge of shoulder to confine water, and corrugated metal pipe at specified intervals buried in the side slopes, to carry off water

14. The earthwork factor is the factor divided into the cut volume to determine the embankment volume. In which one of the following cases will the earthwork factor be less than 1?

_____ a. Glacial till cut
_____ b. Sand and gravel cut
_____ c. Clay cut
__X__ d. Sandstone and shale cut
_____ e. Borrow pit excavation

15. Which of the following soil deposits is the greatest cause of frost heaving in highway cuts?

_____ a. Water-laid silts and clays
_____ b. Water-laid sands
_____ c. Outwash gravels
__X__ d. Moraine deposits
_____ e. Drumlin deposits

16. The principal information gained from the seismic test is:

_____ a. Blasting properties of rock
_____ b. Type of soil
_____ c. Depth to groundwater
__X__ d. Depth to rock
_____ e. Strength of rock

17. A Shelby tube is used for which one of the following operations?

_____ a. Measuring embankment density
_____ b. Consolidation testing
_____ c. Atterberg Limit test
_____ d. Coring rock samples
__X__ e. Obtaining undisturbed soil samples

18. Frost heaves occur when there is a combination of freezing temperatures, groundwater, and frost-susceptible soils. Which of the following soils is most likely to have frost heaves?

    _____ a. Gravel
    _____ b. Organic deposits
    __X__ c. Silty soils
    _____ d. Sand and gravel
    _____ e. Clay soils

19. All footings for structures should be placed at least four feet below final ground surface for which one of the following reasons?

    _____ a. To eliminate settlement
    __X__ b. To eliminate frost heaving
    _____ c. To attain sufficient bearing capacity
    _____ d. To prevent tipping
    _____ e. To reduce settlement

20. Which of the following statements pertaining to the subbase course is <u>not</u> true?

    __X__ a. It provides uniform support for embankment
    _____ b. It distributes pavement and traffic loads to the underlying subgrade soil
    _____ c. It reduces frost heaving
    _____ d. It provides uniform surface for paving
    _____ e. It provides adequate strength to support wheel loads transmitted through pavement

Final Examination Part II -- True or False Statements

INSTRUCTIONS: Write in the space provided the letter T for True or F for False for each of the following statements.

T 1. The principal difference between the behavior of silt and clay is plasticity.

F 2. Plastic soils are easily consolidated by vibrational forces.

T 3. Organic soils left under embankments may cause large settlements in the pavement.

F 4. The hydrometer test is used to determine the amount of gravel in a soil sample.

T 5. The moisture content is defined as the weight of water divided by the weight of soil, times 100.

F 6. The void ratio is defined as the volume of voids divided by the volume of sample.

T 7. The core sampler is used to sample bedrock.

T 8. A permeameter measures the quantity of water flowing through a soil sample in a given time.

F 9. Quicksand is a type of soil deposit.

T 10. The optimum moisture content is the moisture condition in a soil that provides the maximum density with a standard compactive effort.

T 11. Frozen soils cannot be properly compacted.

F 12. Soils may be placed in four-foot layers and be adequately compacted with heavy compaction equipment.

F 13. The magnesium sulfate soundness test is used on all soils placed in embankments.

T 14. The most critical soil deposit to cause erosion problems in highway drainage is silt.

T 15. Structural failures of corrugated metal pipe culverts are often caused by lack of compaction in the backfill.

22497

Final Examination Part III -- Matching Questions (A)

INSTRUCTIONS: Write in the space provided the number of the expression in Column B which is best suited to the expression in Column A.

	Column A		Column B
8	Varves	1.	Measure strength of soil in drill hole
12	Plasticity tests	2.	Measure compression of clay soils
4	A horizon	3.	Measure vibrational settlement
2	Consolidation test	4.	Surface layer of soil
15	Drumlin	5.	Swamp deposit
7	Till	6.	Narrow, winding, steepsided ridge
9	Triaxial compression test	7.	Material deposited by glacier
10	Outwash deposit	8.	Alternate silt and clay layers
1	Vane shear test	9.	Strength of clay soils
11	Gradation curve	10.	Likely source of sand and gravel
13	Berms	11.	Distribution of soil sizes in sample
6	Esker	12.	Atterberg Limits
		13.	Provide embankment stability
		14.	Field measurement of compaction
		15.	Long, streamlined hill

Final Examination Part III -- Matching Questions (B)

INSTRUCTIONS: Write in the space provided the number of the expression in Column B which is best suited to the expression in Column A.

	Column A		Column B
4	Surcharge	1.	Quantity of groundwater flow
6	Equivalent fluid pressure	2.	Portion of highway embankment
1	Q = KiA	3.	Method of measuring settlement
10	Capillarity	4.	Elimination of settlement by overloading
7	Vibratory roller	5.	Rate of water movement
8	Optimum moisture content	6.	Soil pressure on retaining walls
2	Subgrade foundation	7.	Compaction of granular soils
11	Piezometer	8.	Moisture-density relation
9	Wet silt deposits	9.	Construction problems in cuts
15	Earthwork factor	10.	Rise of water above the water table
12	Substitute for dynamite	11.	Measures water pressures in soil
14	Imperfect trench	12.	Ammonium nitrate and fuel oil
		13.	Construction of stabilized shoulders
		14.	Method of pipe installation
		15.	Used in cut and fill quantity computations

UNIT V (14.0901-04)

COMMUNICATIONS

Performance Objectives:

Upon completion of this unit the student will be able to demonstrate to the satisfaction of the instructor, a level of coherence and clarity in oral communications that is adequate for the business office. The student will be able to prepare and write a mailable letter or brief report, from facts provided by the instructor. In a role playing, or other simulated situation, the student will be able to demonstrate correct telephone technique, procedure, and usage. The student will be able to score at least 80% on an objective test covering mail handling and telegraph procedures and use.

Unit Outline:

A. Oral and Written Communications

1. Importance of oral and written communications

2. Importance of good listening

B. Elements of Good Speech

1. Voice control

2. Vocabulary and pronunciation

3. Grammar

C. Speech and Writing Problems

1. Individual analysis

2. Corrective activities

D. Review of Rules for Punctuation, Capitalization, etc.

E. Importance of the Voice in Telephone Usage

1. Control

2. Enunciation

3. Resonance

4. Tone

5. Distance between lip and mouthpiece

ABSTRACT - Developed by the New York State Department of Education and the State Department of Transportation, this teacher's guide is for instructor use in teaching highway design and estimating. The highway technician program, for which this document is intended, is to help relieve the shortage of technicians and engineers by upgrading people employed in lower-level technician programs. The contents of this document, illustrated with line drawings, include 14 lessons, among which are: (1) Highway Classification, (2) Features of Design, (3) Horizontal Alignment, (4) Engineer's Estimate, and (5) Report on Design and Estimate. Each lesson contains objectives, a content outline, questions for review, and an assignment, and each is planned for 2 hours and 40 minutes. A 3-part final examination, a bibliography, and a reference key symbol list are included. Related documents are available as VT 013 359, VT 013 360, and VT 013 061 (all in this issue). (GEB)

Lesson 2 - Sequence of Design (Phase 1)

OBJECTIVES

- To explain the relationship of this unit to previous units in the highway program
- To explain the procedures which lead to the sequential steps necessary to prepare the first phase of preliminary design

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Background	
A. Previous courses	* Point out that the units on basic mathematics, highway drawing, highway surveying, highway planning, and soils and drainage provide a sequence leading to the course in design.
	* Emphasize that this background information will be coordinated with the information contained in this unit on highway design and estimating.
B. Concept of design	* Review briefly (from Unit IV, Preliminary Highway Planning) the reasons which mandate a given design project.
1. Traffic growth	* Point out the tremendous increase in motor vehicles during the past 20 years and briefly recount the three expansion factors of growth. 1. Normal traffic growth 2. Generated traffic 3. Development traffic
2. Highway sufficiency	* Recall the method of road scoring and indicate the important role this plays in deciding whether a highway will be reconstructed.
C. Initiation of design	* Emphasize that as soon as a given project is placed on a design program, the preparation and submission of the program project data (P.P.D.) is the first step taken by the designers.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Context of program project data	* Discuss the submission of program project data, noting that it is a description and a justification of what is proposed. * Distribute prints of the program project data for a project under construction and mention that a rough cost estimate is included in this submission. (Ref. G, p. 3)†
2. Approval of program project data	* Signify that the approval of the program project data by the New York State Department of Transportation's chief engineer and deputy chief engineers (and the Bureau of Public Roads if Federal aid is requested) lays down the ground rules for the design of the highway.
D. Location plan	* Proceed from the approval of the program project data to the actual start of the preliminary design—the location plan.
1. Ordinary reconstruction	* Explain that if the project is merely a widening or a reconstruction along an existing highway with no major relocation contemplated, the route location plan and survey will usually consist of a field inspection, a visual soils investigation, and a review of geodetic maps and record plans of the existing facility.
2. Relocation	* State that if a major reconstruction or new location is contemplated, five steps are taken. (Ref. G, p. 4) 1. A 200-ft. scale topographic map for the general corridor area is required and is obtained either by photogrammetrics or conventional survey.

†Reference citations are shown on page 220.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	2. Traffic information about all critical locations is necessary to implement the counts given on the program project data. 3. A preliminary soils investigation is required. 4. Any unusual condition such as stream channels and railroads must be investigated. 5. A location plan must be prepared in both the vertical and horizontal alinement.
3. Approval of the location plan	* Point out that the location plan is submitted to the deputy chief engineer of highways for review. * Add that a new route location should provide maximum service to the traveling public at minimum construction and maintenance cost and the least disruption cost to property. (Ref. G, p. 4)
E. Public hearing	* Explain that if a plan is approved and the project involves Federal participation, a public hearing is scheduled and advertised. * Show the importance of a public hearing by stating that suggestions given or questions raised may warrant review of the alinement.
F. Survey	* State that after the public hearing is held, a survey is begun either by conventional methods or by photogrammetrics. (Ref. A, pp. 312-318; Ref. G, p. 5)
II. Design Assignment	* Point out that the survey information now enables a squad of engineers and technicians to prepare a preliminary plan.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
E. Passing sight distance	* Note that passing sight distance (P.S.D.) will be covered in a later lesson. * Mention that a rural design class 5 highway permits only 20 percent of the highway to have less than 1500 ft. of passing sight distance.
F. Design speed	* Indicate that design speed is a basic principle of highway planning and that it is a function of traffic capacity. * Note that the rural design class 5 has a design speed of 60 m.p.h. with a running speed at peak hours of 45 m.p.h.
G. Traffic composition	* State that trucks usually make up between zero and 20 percent of the traffic. * Point out that a rural design class 5 highway should be adequate to accommodate a maximum truck traffic of 10 percent.
H. Clearance lanes	* Explain that clearance lane criteria for structures are indicated under bridge notes. * Note that here also criteria are being significantly affected by safety considerations.
1. Safety walks	* Point out that contrary to bridge-note 1 safety walks are not recommended for any structure. (Ref. L, p. 39)
2. Lane width	* Emphasize that all bridges will carry the full roadway section across the structure which will consist of the pavement widths plus the full shoulder width (the shoulder width must be a minimum of 6 ft.). * Note that a brush curb encroaches 6 in. on the clearance.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. General notes	* Comment on the general notes listed on the classification chart.
1. Minimum width	* Note that the travel width of pavement is never under 20 ft. although class 9 and 9M call for 18 ft. by traffic criteria but they are considered special cases.
2. Design elements	* State that the other general notes will be covered in the functional design criteria later in this unit.
J. Nonstandard classifications	* Emphasize that although standards are the key to design, sometimes exceptional conditions make it necessary to deviate from the recommended criteria. * Point out that if a different design from the one called for in the chart is used, permission must be obtained from the deputy chief engineer of highways. * Mention that the next lesson will provide ample opportunity for discussion on the evasion of criteria.
III. Traffic Composition	* State that the physical characteristics of vehicles and the number of each kind using the highways are positive controls in geometric design. (Ref. A, pp. 123; Ref. B, pp. 69-86)
A. Vehicle classification	* Note that all vehicles have been classified into two categories, (passenger cars and trucks), and that a design vehicle for each type has been selected by the AASHO.
B. Design vehicle	* Define a design vehicle as one whose weight, dimensions, and operating characteristics are used to establish highway design controls. * Add that for the purpose of geometric design, the design vehicle should be one with larger dimensions

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	and a smaller minimum turning radius than almost all vehicles in its class.
1. Passenger car	* Identify the passenger car classification with the symbol P and mention that all information is based on the 1962 production year.
a. Length	* Note that the length of the design passenger car is 19 ft. overall on an 11-ft. wheelbase with a rear overhang of 5 ft. and a front overhang of 3 ft.
b. Minimum turning radius	* State that the minimum turning radius is the radius of the turning path of the outside front wheel. This radius for the design passenger car is 24 ft. * Explain how the amount of overhang of a vehicle is related to its minimum turning radius.
c. Width and height of vehicle	* Point out that the overall width is 7 ft., the out-to-out width between tires is 6 ft. and the height is 4 to $5\frac{1}{2}$ ft.
2. Single unit trucks and buses	* Identify single unit trucks and busses with the symbol SU and note that all information is based on a survey of state loadometer stations in 1959.
a. Length	* State that the SU design vehicle is 30 ft. long overall on a 20-ft. wheelbase with overhangs of 4 ft. in front and 6 ft. in the rear.
b. Width and height	* Mention that the width of the SU design vehicle is $8\frac{1}{2}$ ft. No designation is used for height as most states limit vehicle height to $13\frac{1}{2}$ ft.
c. Minimum turning radius	* Indicate that the minimum turning radius of the SU design vehicle is 42 ft.

INTRODUCTION

The rapid expansion in the building of state and Federal highways has caused a serious shortage of qualified technicians and engineers for planning, supervising, constructing, and maintaining highways. The New York State Department of Transportation and the State Education Department have collaborated in planning the Highway Technicians Program to overcome this shortage.

This program is expected to help provide the additional technicians and engineers by upgrading people employed in the lower-level technician jobs. This Teacher's Guide, *Highway Design and Estimating*, and the others in the program are intended primarily to improve the skills and technical knowledge of those technicians.

Local boards of education and other sponsors of adult education programs are being encouraged to offer the courses in this program as part of occupational education. Besides attracting students from the Department of Transportation in the job categories mentioned above, students will also be drawn from the public works departments of counties, cities, and towns; in addition, technicians, estimators, and junior engineers employed by construction contractors will be found in these classes.

The units of the Highway Technicians Program have been planned to be taught in numerical sequence. Enough subject matter has been included in each lesson for about 2-1/2 hours of classroom instruction. The total length of the course, however, may be adjusted to fit in with the prior experience and education of enrollees.

The units in the Highway Technicians Program are:

Unit I.	Basic Mathematics Review
Unit II.	Highway Drawing
Unit III.	Highway Surveying
Unit IV.	Preliminary Highway Planning
Unit V.	Soils and Drainage
Unit VI.	Highway Design and Estimating
Unit VII.	Highway Construction and Inspection
Unit VIII.	Highway Structures
Unit IX.	Highway Maintenance

EDWARD L. BOOTH, *Chief*
Bureau of Occupational Extension and Industrial Services

C. THOMAS OLIVO, *Director*
Division of Industrial Education

EXHIBIT B

HIGHWAY DESIGN AND ESTIMATING

Lesson 1 - Introduction

OBJECTIVES

- To become acquainted with class members
- To provide a general description of the course

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Orientation	
A. Teacher introduction	* Print the name of the course and your name on the chalkboard and give a brief description of your activities and experience.
B. Purpose of course	* Explain that the course is being given primarily to increase the knowledge of technicians in the design office and in the field so that they may upgrade themselves.
C. Group evaluation	* Have each student introduce himself and volunteer such information as name, occupation, and where employed. * Distribute cards with spaces for name, address, phone number, occupation, place of employment, previous schooling, and units in this program already taken.
D. Course prerequisites	* State that the students must know geometry and trigonometry and should have completed the five preceding units because this unit utilizes all the information covered previously: 1. Basic Mathematics Review 2. Highway Drawing 3. Highway Surveying 4. Preliminary Highway Planning 5. Soils and Drainage

Lesson 2 - Sequence of Design (Phase 1)

OBJECTIVES

- To explain the relationship of this unit to previous units in the highway program
- To explain the procedures which lead to the sequential steps necessary to prepare the first phase of preliminary design

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Background	
A. Previous courses	* Point out that the units on basic mathematics, highway drawing, highway surveying, highway planning, and soils and drainage provide a sequence leading to the course in design. * Emphasize that this background information will be coordinated with the information contained in this unit on highway design and estimating.
B. Concept of design	* Review briefly (from Unit IV, Preliminary Highway Planning) the reasons which mandate a given design project.
1. Traffic growth	* Point out the tremendous increase in motor vehicles during the past 20 years and briefly recount the three expansion factors of growth. 1. Normal traffic growth 2. Generated traffic 3. Development traffic
2. Highway sufficiency	* Recall the method of road scoring and indicate the important role this plays in deciding whether a highway will be reconstructed.
C. Initiation of design	* Emphasize that as soon as a given project is placed on a design program, the preparation and submission of the program project data (P.P.D.) is the first step taken by the designers.

TO THE INSTRUCTOR

Highway Design and Estimating is the sixth in a series of nine courses which provide fundamental information to prepare your students for advanced work in highway planning, design, construction, and maintenance. Follow the content as closely as possible. Keep in mind that topics other than those in this unit are covered in other units of the Highway Technician Program. The units are planned to be given in numerical order as adult or continuing education courses.

In general, lessons in each of the units are planned for a session of 2 hours and 40 minutes. You may adjust this period to fit the class level, time schedule, and classroom situation. This course contains 14 lessons.

Plan each lesson before you present it to your class. You will need to plan classwork, discussion, and review. The left-hand column of each lesson contains suggested topics to be covered. The right-hand column gives accepted techniques, methods, and tips, as well as related information which should help you achieve effective teaching. Also this column shows page references for selected books for which the complete citations and symbols are given on page 220. Specific assignments are given at the end of each lesson. You should preview each lesson and arrange for needed visual aids and reference material in advance of the class.

Use the chalkboard, overhead projector, charts, diagrams, and other visual aids to clarify the material being presented. Duplicate for student use any important reference material. Give typical job situations as illustrations whenever possible.

Give a summary of key points at the end of each lesson. Also refer to past and future lessons and remind the students of needed references and other materials for the next lesson. Emphasize to the students that answers to the questions for each lesson provide a good summary of the important points.

A final examination is provided at the end of this Guide. The questions are derived from the basic material given in the lessons and the difficulty of each type is in proportion to the importance placed on any particular phase. The questions are in the form of matching, completion, and multiple choice and should be completed in about 1 hour. The correct answers given in each case are for the instructor only, and the spaces are to be left blank in presenting the questions to the students.

As you use this course guide, you may have ideas for improving its content. Any suggestions you wish to make should be addressed to the New York State Education Department, Bureau of Continuing Education Curriculum Development, Albany, New York 12224.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Previous experience	* Indicate, however, that experience comparable to the coverage in the first five units is satisfactory.
II. Required Student Equipment	* Point out that this unit will require very little equipment but that two textbooks will be used.
A. Textbooks	* Write on the chalkboard the name, author, publisher, and copyright date of both texts.
1. *Highway Engineering*	* Show a copy of the 3rd edition of *Highway Engineering* by L. J. Ritter and R. J. Paquette, published by the Ronald Press Company in 1967. * State that this is a college textbook used to teach the fundamentals of highway engineering.
2. *A Policy on Geometric Design of Rural Highways*	* Exhibit a copy of *A Policy on Geometric Design of Rural Highways*, published in Washington, D.C. by the American Association of State Highway Officials in 1966. Emphasize that a designer should never be without a copy of this book. * Point out that the content of this book is limited to the geometric features of highway design as distinguished from structural design. * Ask the students to sign a sheet for the textbooks so that a group order may be made.
B. Looseleaf notebook	* Suggest that the students use a looseleaf notebook for notes, problems, and for printed matter distributed occasionally.
C. Engineer's scale and small triangles	* Indicate that two small triangles and an engineering scale with 10, 20, 40, and 50-ft. scales are necessary equipment.
III. Highway Design	* State that this course covers functional design.

22512

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Course description	* Explain briefly the subject matter covered in each lesson of this unit.
1. Introduction to the course	* State that the first lesson briefly outlines the content of the course.
2. Sequence of design (first phase)	* Point out that certain rudiments of design have already been discussed in previous units and that these basic ideas will combine with new concepts in Lesson 2 to form a sequential pattern.
3. Classification of highways	* Explain that Lesson 3 covers the important link between highway planning and highway design: the classification of a given highway. * Mention that the chart entitled *Geometric Highway Standards for Urban, Primary, and Secondary Highways* is used to establish design criteria and will be analyzed in this lesson.
4. Features of design	* State that Lesson 4 introduces the concept of functional design and covers subjects such as stopping sight distance, passing sight distance, lateral sight distance, and lane width. * Note that Lesson 5 continues instruction about design features and covers curbs, medians, pavement surfaces, crowns, and shoulders.
5. Horizontal alinement	
a. Control of curvature	* Point out that Lesson 6 is a study of the relationship between speed and curvature. The forces at work in circular motion will be used to control the curvature of highways.
b. Superelevation runoff	* Add that Lesson 7 is an additional refinement of horizontal alinement in which the basic mechanics of motion are applied in a practical sense. The methods of achieving full bank are discussed with the emphasis on the use of superelevation.

F. The Telephone Directory

1. Alphabetical directory

2. Classified directory

3. Out-of-town directory

G. Types of telephone services

H. Handling Calls

1. Incoming calls

2. Outgoing calls

I. Types of Telegraph Services

J. Preparation of Messages

1. Choice of class of service

2. Use of special words and code

3. Cost of transmission

4. Time differences (zones)

K. Importance of Mail

L. Procedures for Handling Mail

M. Classification of Mail and Rates

N. Postage Equipment and Supplies

1. Postage meters and scales

2. Automatic addressing systems

Supplemental Teaching Aids:

Many good resource books applicable to this unit are available, particularly in the field of special education. Others are the following: Communicating Facts and Ideas in Business, Leland Brown, Prentice-Hall, Englewood Cliffs, N.J., 1961, Business English in Communications, Himstreet, Porter and Maxwell, Prentice-Hall, Englewood Cliffs, N.J., 1964.

A series of three programmed texts by Joseph C. Blumenthal are available from Harcourt, Brace, and World. A great deal of free material is available from Western Union including the film "Telegram for America". Pitney-Bowes, Inc. distributes two publications on mailing machines entitled How to Increase the Prestige of Your Mail and 29 Timely Mailing Tips.

Training Time 35-45 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
6. Elements of horizontal alinement	* Explain that Lesson 8 is a summary guide for general horizontal controls together with the elements of widening, horizontal sight distance, intersections, grade separations, and speed-change lanes.
7. Vertical alinement (criteria and controls)	* State that in Lesson 9 a brief review of vertical curvature will be given with special emphasis on design criteria. Add that general controls for vertical alinement design will be studies together with combinations of horizontal and vertical controls.
8. Typical sections and standard structure sheets	* Note that in Lesson 10 the typical section (a quick analysis of the cross section of a highway) will be investigated and studied. * Add that the use of the standard structure sheets will also be discussed.
9. Geometric auxiliaries	* Point out that in Lesson 11 the geometric auxiliaries of a design will be studied with respect to the trend in lighting, signing, marking, landscaping, and delineation.
10. Sequence of design (second, third, and fourth phases)	* Correlate Lesson 12 with Lesson 2, noting that in phase 2 the centerline is controlled by mathematics, the cross section work is completed, and the layout design is prepared. * Mention that phase 3 is the preparation of the contract plans and that phase 4 is the preparation of the report on design and estimate.
11. Engineer's estimate	* Explain that in Lesson 13 the engineer's estimate will be examined with special emphasis given to the measurement and payment of contract items in accordance with Department of Transportation specifications.
12. Report on design and estimate	* Summarize the Report on Design and Estimate as being a consolidation of

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	all the pertinent data which make up a design project.
13. Final examination	* State that an examination will be given at the end of this unit to point out any weak areas. * Indicate that a seminar will follow the examination for the purpose of correcting papers and for open discussion of the more important areas in the unit. * Remind the students to bring their notebooks to the next class and emphasize the need for punctuality and regular attendance.

ASSIGNMENT

Read pages 3-32 and 52-69 in Ref. A.

INSTRUCTOR'S NOTES

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Preliminary plans	* State that preliminary plans at appropriate scales are prepared and include the following: 1. Typical sections 2. General drainage 3. Geometry of interchanges and ramps 4. Bridges (information submitted to the deputy chief engineer of bridges)
B. File information	* Note that the engineer who is called on to design the project may be unfamiliar with the preliminary steps so he should study the project files.
1. Correspondence	* Indicate that all letters which relate to the conception of the project must be read.
2. Program project data	* Recommend that all the pertinent information concerning design guides in the program project data be studied.
3. Route studies	* Explain the need for studying the history of the road including sufficiency reports, previous work done on the road, and the extent of right-of-way purchases. * Mention that it is helpful to search the records for the dedicated width of the right-of-way and note that in many design offices a complete investigation has been made to determine the dedicated widths of all highways in the district. * Emphasize the importance of actually walking the approved route.
4. Survey notes	* Have students check survey data books for proper indexing so that they may be drawn from and returned to the file room without confusion.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
III. Preliminary Line and Grade	* Advise that every project begins with a preliminary line and grade, the foundation of a design. (Ref. A, pp. 318-320)
A. Cross sections	* Point out the process used to draw cross sections from the base-line level notes.
1. Plotting	* Note that these sections are plotted on coordinate paper to a horizontal scale of 1 in. equals 5 ft. and to a vertical scale of 1 in. equals 5 ft.
2. Coverage	* Insist that this coverage should show tree lines, buildings, barns, drives, intersecting roads, curbs, centerlines, foundations, manholes, culverts, sewers, and wells.
3. Checkpoint	* State that all cross sections are checked, inked, marked with the base-line station, and verified for the signatures of the plotter and checker.
B. Base-line topography	* Clarify the process of plotting, checking, and inking the base line with its angular and distance control, together with all the topography shown in the transit notes.
	* Specify that this is done for the 1 in. equals 200-ft. scale plan and also for the 1 in. equals 50-ft. scale plan.
C. Base-line profiles	* Designate the next step as plotting, checking, and inking the base-line profile at 1 in. equal to 200 ft. horizontally and 1 in. equal to 20 ft. vertically for use with the 200-ft. scale plan.
	* Note that the 200-ft. scale plan is used for tentative line and grade but that the 50-ft. scale plan (for rural areas) and the 20-ft. scale plan (for urban areas or for densely populated rural areas) is used for the actual design.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Mention that when the 20-ft. scale plan is used, the corresponding profile scale is 1 in. equals 20 ft. horizontally and 1 in. equals 5 ft. vertically.
1. Form	* State that this work is done completely on reproducible material and that the profiles are on a continuous roll of coordinate paper.
2. Controls	* Review the importance of indicating control points with elevation and description.
D. Tentative centerline	* Note the need of studying the 200-ft. scale plan and profile and of actually walking the new route before drawing the tentative centerline and gradeline.
1. Soils report	* Explain that a soils report is obtained by furnishing a print of the tentative line and grade to the soils engineer.
2. Line shift	* Mention that the tentative line is shifted in accordance with soils reports, profile controls, and the right-of-way considerations.
E. Design centerline	* Stipulate that the centerline is designed on the 50-ft. scale plan and profile, while the templates of the typical section are fitted on the cross sections for the best location both vertically and horizontally. * Indicate that all control points are acknowledged in this operation. * Note that this step and the following steps involve design factors covered later in this unit.
1. Controls	* State that obstacles such as cattle passes, swamps, peat bogs, rock ledges, driveways, service roads, utilities, and special right-of-way restrictions located in the path of the centerline are noted on the 50-ft. scale plan.

Lesson 3 - Highway Classification

OBJECTIVES

- To show how the elements of highway planning apply to functional design
- To become familiar with the system of classifying highways

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Functional Design	* Mention that functional design is used to make the highway as nearly perfect as possible for both the vehicle and the driver.
A. Definition	* State that functional design applies to the motion and operating characteristics of vehicles and to the ability and psychological behavior of the operator.
B. Objective	* Indicate that functional design aims at providing greater traffic capacity and efficiency while maintaining safety. (Ref. C, section 22, p. 6)†
C. Elements	* Note that the functional design of a highway involves the design of only the visible features which will be covered in later lessons, namely: • Vehicle speed • Human reaction time • Space and time • Dynamics • Centrifugal and centripetal forces • Vehicle characteristics • Human behavior and psychology • Alinement • Grades • Right-of-way • Curvature • Superelevation • Channelization • Pavement friction

† Reference citations are shown on page 220.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Adjustments	* Point out that sight distances are checked and that line and grade are adjusted to obtain the proper percentage of passing sight distance as required by the classification chart.
F. Bridges	* Note that the district bridge section gives bridge and culvert topography, level notes, and approximate location of any structures.
G. Field inspections	* State that all necessary field inspections for line and grade are made and that special drainage problems, buildings built after the survey, and sites for cattle passes and utility relocations are investigated.
1. Alterations	* Add that both line and grade are shifted in accordance with this information.
H. Conference	* Note that a conference is then scheduled with representatives of the various departments involved for a final decision.
1. Approval by deputy chief engineer	* Indicate that prints of the tentative centerline on the 200-ft. scale plan and profile and typical sections that are to be used are prepared for final approval by the deputy chief engineer.
2. Approval by Bureau of Public Roads	* Note that these plans will be examined by the Bureau of Public Roads who will be represented at the conference if Federal aid is involved.
3. Plans for Right-of-Way Department	* State that a 200-ft. scale plan is submitted to the District Right-of-Way Department for investigation of land deeds and title searches.
IV. End of First Phase	* Emphasize that submission of the 200-ft. scale plan and profile to the deputy chief engineer for approval marks the end of the first phase of design.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Mention that despite its small scale the plan and profile submitted should be as accurate as possible.
A. Checklist	* Point out that the small-scale plan and profile are checked for the following items: 1. Scaling 2. Original ground elevations 3. Equalities 4. Property lines and corners 5. Maximum grades and curves 6. Town, county, city, or village lines 7. Road names and numbers 8. North arrow 9. Limits of the contract * Exhibit and discuss a 200-ft. scale plan and profile which has been prepared for submission.
B. Contract plans	* State that the actual design of the project begins at this point. It is here that the myriad of details are worked out. (Ref. G, p. 6)

QUESTIONS FOR REVIEW

1. How does road scoring assist in the determination of priority for construction of a highway?

2. Name six items which are classified on the program project data sheets.

3. What is the extent of a route location survey?

4. Explain why a public hearing is held.

5. How does the engineer prepare himself when placed in charge of the design of a project?

6. Discuss the importance of cross sections for a given base line.

7. Why is a 200-ft. scale plan and profile necessary for a design when it is a known fact that the plan and profile must be made on a 50-ft. scale plan?

8. Name three major reasons why a centerline would be shifted either vertically or horizontally, or both.

9. List six factors which should be checked on the small-scale plan.

10. What factors would necessitate field inspections for a design alinement?

ASSIGNMENT

Read pages 121-132 in Ref. A, and pages 69-133 in Ref. B.

INSTRUCTOR'S NOTES

22524

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	• Pavement width • Shoulders • Pavement cross section • Guide railing • Roadside landscaping • Lighting • Reflectorization • Signs • Stopping sight distance • Passing sight distance • Marking • Signalization • Utilities • Delineators • Rest areas • Sidewalks
II. Highway Classification	* Discuss briefly the design hour volume (DHV) and indicate that a highway is classified according to this count.
A. Design class	* Explain the analysis of design classes. (Ref. D) 1. Urban design class 1 to 7 (level or rolling) for a DHV of 4400 to 550 or less 2. Rural design class 1 to 9 (level or rolling) for a DHV of 3000 to 20 3. Mountainous design class 5M to 9M (hilly or mountainous) for a DHV of 350 to 20 * Point out that the design class confines the project to specific standards or limits.
III. Design Standards	* Distribute a copy of Ref. D. to each student. Explain that the chart is the key to the design of a modern highway.
A. Width	* Note that in the columns under width data in Ref. D, standards for five items are shown.

UNIT VI (14.0901-07)

FINANCIAL ACTIVITIES

Performance Objectives:

Upon completion of this unit the student will be able to score at least 80% on an instructor developed objective test covering the handling and verifying of forms involved in ordering, receiving, selling, and general financial records. Also covered in this test should be common reports required by governmental agencies.

Unit Outline:

A. Importance of the Need of Financial Records

B. Types of Records

1. Personnel

2. Payroll

3. Sales and purchases

4. Inventory

5. Taxes

6. Financial statements

7. Petty cash

8. Budgets

9. Credit applications

Supplemental Teaching Aids:

An excellent resource person for this unit is a staff member from the college business office. Free or inexpensive information is available from the Massachusetts Bankers Association, [illegible] High St., Boston, 02110. Of some value is the comic book- The Story of Checks, available from the Federal Reserve Bank of New York.

Training Time 8-10 hours

2221

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	1. Pavement width or travel way 2. Travel lane 3. Parking lanes in addition to the travel lanes 4. Shoulder or clearance lanes 5. Width of right-of-way
	* Explain that a rural design class 5 highway is an example of an average highway. Since this design is classified as 500-vehicles per hour one way, it requires a 24-ft. travel pavement width consisting of two lanes at 12 ft. each, no parking lanes, 10-ft. shoulders and a minimum right-of-way of 120 ft.
	* State that at the present time it is recommended that a 12-ft. shoulder and a 12-ft. pavement be used for any highway with a DHV of 100. This may become part of the standards in the near future.
B. Gradient	* Point out that in the column of maximum grades (shown in percent) the grades increase as the traffic count decreases.
	* Observe that a rural design class 5 highway limits the maximum grade at 5 percent which is also the maximum value for urban classes 4, 5, 6, and 7 and rural classes 3 and 4.
C. Horizontal curvature	* State that in the column of maximum curve (shown in degrees) the allowed curvature increases as traffic decreases.
	* Note that a rural design class 5 highway is limited to a 5°-curve as are rural classes 3 and 4.
D. Stopping sight distance	* Explain briefly the meaning of stopping sight distance (S.S.D.) and mention that this will be taught and computed in a later lesson.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
4. Application	* Find the stopping distance on a wet pavement when the design speed is 60 m.p.h. (actual speed 52 m.p.h.). * Recall that the perception time and brake reaction time is assumed to be a total of $2\frac{1}{2}$ seconds. 60 m.p.h. = 88 ft./sec. $\frac{52}{60}$ x 88 ft./sec. = 76 ft./sec. 76 ft./sec. x 2.5 sec. = 191 ft. $d = \frac{V^2}{30f}$ $= \frac{52 \times 52}{30 \times 0.30}$ = 300 ft. * State that the stopping distance of the vehicle is 191 ft. plus 300 ft. for a total of 491 ft. This is rounded off to 475 ft. for design purposes.
5. Design Criteria	* Indicate that the safe stopping sight distances, rounded for design, are as follows: 1. 200 ft. at 30 m.p.h. 2. 275 ft. at 40 m.p.h. 3. 350 ft. at 50 m.p.h. 4. 475 ft. at 60 m.p.h. 5. 550 ft. at 65 m.p.h. 6. 600 ft. at 70 m.p.h. 7. 675 ft. at 75 m.p.h. 8. 750 ft. at 80 m.p.h.
B. Minimum stopping sight distance on grades	* Explain the effect of a grade on the stopping ability of a vehicle. * Note that the percent of grade divided by 100 (g) is added on a plus grade (and subtracted on a minus grade) to f in the denominator of the formula for braking distance.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	$d = \frac{V^2}{30(f \pm g)}$
1. Application	* Find the stopping distance on a 6-percent upgrade using the same basic information given in the preceding problem. * Note that the distance traveled during the perception time and brake reaction time remains at 191 ft. $d = \frac{52 \times 52}{30(0.30 + 0.06)}$ $= \frac{2704}{10.8}$ = 250 ft. * State that the stopping distance of the vehicle is 191 ft. plus 250 ft. for a total of 441 ft. * Find the stopping distance on a 6-percent downgrade using the same basic information given in the preceding problem. * Point out that the distance traveled during the perception time and brake reaction time remains at 191 ft. $d = \frac{52 \times 52}{30(0.30 - 0.06)}$ $= \frac{2704}{7.2}$ = 376 ft. * Indicate that the stopping distance of the vehicle is 191 ft. plus 376 ft. for a total of 567 ft.
C. Minimum passing sight distance (two-lane highway)	* Define the minimum passing sight distance as the distance required for a vehicle to safely pass another vehicle moving in the same traffic lane. (Ref. A, pp. 157-161; Ref. B, p. 140)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	that essentially the railing is used to guide a vehicle away from a hazard and to guard it from disaster.
A. Objective	* Mention that guide railing is used to reduce the hazard to traffic, not to protect any part of the highway. (Ref. L, p. 29) * Point out that guide railing is used only where the result of striking an object or leaving the highway would be more severe than the consequences of striking the guide railing.
B. Research	* Indicate the amount of research that has been conducted to develop a proper type of rail for a given condition. * State that up to the present time different types of railing have been used successfully, but now problems are being encountered with the transition from one type to another.
C. Uses	* Explain that guide railing is used at points of potential hazard such as: 1. Fixed objects close to the pavement 2. Fills on steep grades 3. Long through fills 4. Fills on sharp curvature 5. Along water courses 6. Escarpments 7. Deep ditches in cuts 8. Ledge rock in cuts
1. Protection on fills	* Mention that the following criteria indicate that guide railing should be used when fill height exceeds: 1. 10 ft. for a 1 on 2 slope 2. 20 ft. for a 1 on 3 slope 3. 40 ft. for a 1 on 4 slope 4. 50 ft. for a 1 on 5 slope 5. 60 ft. for a 1 on 6 slope

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Explain that the height of fill is measured vertically at the point 30 ft. out from the edge of pavement to a point on the original ground.
D. Edge distance	* Indicate that the edge distance from the pavement to the guide railing is a 30-ft. clear distance for a 1 on 6 slope plus 2 ft. 3 in. * Note that the explanation of the clear distance will be discussed in a later lesson. * Mention that these are guides and that they must not be confused with hazard areas.
E. Design	* State that guide railing is designed to deflect a vehicle so that it continues to move at reduced velocity along the rail. (Ref. B, p. 243) * Discuss the various types of guide railing as shown on the large scale prints of standard structure sheets. (Ref. H)
1. Cable guide railing	* Explain that cable guide railing is $\frac{3}{4}$-in. round cables connected to wood or steel posts. The cable ends must be securely anchored. (Ref. H, 64-2R1, 66-14A-R1 and 66-14B-R1) * Point out that posts are spaced 16 ft. on curves less than 4° and 12 ft. on curves between 4° and 6° and 8 ft. on curves between 6° and 8°.
2. Box beam guide railing	* Add that a box beam guide railing is a continuous hollow structural steel tube, 6 in. square. * Mention that this tube is mounted on 3-in. I-beam steel sections at 6-ft. intervals. (Ref. H, 66-15)
3. Box beam median barrier	* Note that the box beam median barrier is a 6 in. by 8 in. tube. (Ref. H, 65-16R2)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Note that the minimum passing sight distance is determined for a single vehicle passing a single vehicle.
1. Assumptions	* Point out the assumptions that must be made before any computations are attempted. (Ref. B, p. 141) 1. The overtaken vehicle travels at a uniform speed. 2. The passing vehicle has reduced speed and trails the overtaken vehicle as it enters a passing section. 3. When at the passing section, the driver needs time to perceive the clear passing section and to react before he begins his maneuver. 4. Passing is accomplished under a delayed start and a hurried return. The passing vehicle accelerates during the maneuver and its average speed during the occupancy of the left lane is 10 m.p.h. higher than that of the overtaken vehicle. 5. When the passing vehicle returns to its lane, there is a suitable length between it and an oncoming vehicle in the other lane.
2. Component parts	* Note that the minimum passing sight distance is actually the sum of four distances. Sketch on the chalkboard the position of the four distances. (Ref. B, p. 143) 1. Distance traversed during the preliminary delay period - d_1 2. Distance traversed while the passing vehicle occupies the left lane - d_2

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	3. Distance between the passing vehicle and the opposing vehicle at the end of the maneuver - d_3 4. Distance traversed by an opposing vehicle for two-thirds the time the passing vehicle occupies the left lane - d_4
3. Design criteria	* Indicate that the minimum passing sight distances used are as follows (Ref. B, p. 145): 1. 1100 ft. at 30 m.p.h. 2. 1500 ft. at 40 m.p.h. 3. 1800 ft. at 50 m.p.h. 4. 2100 ft. at 60 m.p.h. 5. 2300 ft. at 65 m.p.h. 6. 2500 ft. at 70 m.p.h. 7. 2600 ft. at 75 m.p.h. 8. 2700 ft. at 80 m.p.h.
D. Minimum passing sight distance (three-lane highway)	* State that the minimum passing sight distance for a three-lane highway is shorter than that required for a two-lane highway and is equal to d_1 plus d_2 plus d_3. * Point out that the three-lane highway is now being marked and signed as a two-lane road. * Refer to the standards chart and explain that only a percentage of the required minimum passing sight distance is necessary for a particular design. (Ref. D)
E. Minimum sight distance at intersections	* Mention that the minimum sight distance at an intersection should give an approaching driver an unobstructed view of the entire intersection and a portion of the intersecting highway sufficient to permit the safe operation of the vehicle. (Ref. B, pp. 392-401)
1. Minimum sight triangle	* Explain the minimum sight triangle by drawing a simple sketch on the

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
4. Beam type guide railing	* Indicate that the beam type guide railing is a section of 12-gage steel, 14 in. wide, that is curved and mounted on railroad rails, wood, or concrete posts spaced 12 ft. 6 in. apart. (Ref. H, 63-17) * State that when the beam type railing is used as a median barrier the posts are spaced 6 ft. 3 in. apart. (Ref. H, 66-17A)
F. Deflections	* Point out that a guide railing is selected because of its deflection capabilities. * Mention that the best type of guide railing is one where the posts give under impact but the railing holds the vehicle. * Point out that usage is based primarily on the amount of space available for deflection. * Suggest that tests indicate that at 60 m.p.h. with a 25° angle of impact, the following deflections take place: 1. A box beam on a 6 in. by 8 in. post deflects 2 ft. 2. A box beam on a 6 in. by 6 in. post deflects 4 ft. 3. A W section on a 3-in. I-beam post deflects 6 ft. 4. A cable railing deflects 8 ft.
G. Approach end	* Emphasize that the approach end of any guide rail is the most formidable roadside obstacle confronting traffic. * Recommend that the approach end be flared away from the pavement and turned down into the ground.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
H. Bridge approaches	* Mention that bridge approaches must be protected with box beam railing connected in line with the bridge railing. * Point out that bridge pylons are removed from existing bridges and not built on new bridges so that the flow line of the guide railing can be continuous.
IV. Pavement Surface	* Indicate that all highway pavement surfaces are grouped into three general types. (Ref. B, p. 222)
A. High type	* Add that the high type surface is built for a large volume of traffic and should have smooth riding qualities and good nonskid properties in all weather. * State that a smooth surface offers little frictional resistance to the flow of water. * Explain that the surface should retain its shape with a minimum of maintenance. The retention of shape guarantees the pavement without concern for raveled edges. * Note that the high type surface is usually a concrete pavement and often referred to as a rigid type of pavement. * Mention that the strength and stability of this type of pavement has a psychological effect on driver behavior.
B. Intermediate type	* Indicate that the intermediate type surface is usually bituminous and that it can vary from an excellent road structure to a mere surface treatment. It is often described as a flexible type of pavement.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Semitrailer combinations	* Note that because of the variances in wheelbases, semitrailer combinations are separated into two wheelbase groups.
a. WB-40	* Mention that the WB-40 design vehicle is 50 ft. long on a 40-ft. wheelbase with a semitrailer wheelbase of 13 ft. and an overall width of $8\frac{1}{2}$ ft. * Indicate that the minimum turning radius is 40 ft.
b. WB-50	* Add that the WB-50 design vehicle is 55 ft. long on a 50-ft. wheelbase with a semitrailer wheelbase of 20 ft. and an overall width of $8\frac{1}{2}$ ft. * Note that the minimum turning radius is 45 ft.
IV. Design Speed	* Define design speed as the speed determined after taking design and physical features of a highway into account. (Ref. B, pp. 87-98) * State that design speed is the maximum safe speed that can be maintained over a specified section of highway under conditions so favorable that the design features of the highway influence vehicle operation. * Indicate that the choice of a design speed is influenced by the character of the terrain, the extent of manmade features, and economic considerations.
A. Relationship to geometrics	* Note that as high a design speed as possible should be used in order to insure mobility and efficiency with a high degree of safety. * State that once design speed is selected, the complete geometrical design must be directly related to it.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Point out that features like curvature, superelevation, and sight distances directly affect design speed while lane and shoulder widths and clearance affect speed.
B. Design speeds used	* State that from this point on all references to design speed shall be made in accordance with the following speeds in miles per hour: 30, 40, 50, 60, 65, 70, 75, and 80.

QUESTIONS FOR REVIEW

1. Describe what is meant by the geometrics of a highway.
2. Name 25 elements of geometrical design.
3. Why are highway designs divided into different categories?
4. What is the maximum grade allowed on a rural design class 5 highway?
5. What is the maximum horizontal curvature allowed on a rural design class 5 highway?
6. What is the maximum truck traffic expected on a rural design class 5 highway?
7. How can a particular design deviate from the standards of the classification chart?
8. What is the concept on which functional design is based?
9. What are the listed design speeds used in the United States?
10. How is design speed directly related to horizontal curvature?
11. What is meant by design speed and how is it selected?
12. Why is it important to know the amount of overhang in a vehicle?
13. Describe how the minimum turning radius is measured.

ASSIGNMENT

1. Learn the classification criteria for the rural design class 5 highway.
2. Read pages 154-163 in Ref. A, and pages 134-151, 225-227, and 392-401 in Ref. B.

Lesson 4 - Features of Design

OBJECTIVES

- To provide a description of functional design with respect to various geometric features
- To set the basis for design criteria

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Sight Distance	* Indicate that a highway must provide sufficient clear vision so that a driver can avoid hitting unexpected obstacles and pass slower vehicles without danger. This length of highway visible to the driver is called sight distance. (Ref. A, p. 154 -155; Ref. C, section 22, p. 8)†
A. Minimum stopping sight distance	* State that the minimum stopping sight distance should be long enough to enable a vehicle at or near the design speed to stop before reaching an object in its path. This is often called the nonpassing sight distance. * Point out that this distance is a minimum and that a greater length is desirable. * Indicate that the minimum stopping sight distance is the sum of the distances traveled by a vehicle during: 1. Perception time 2. Brake reaction time 3. Braking
1. Perception time	* State that the time lapse from the instant a driver sights an object to the instant he decides to stop is called perception time. (Ref. B, pp 134 - 135). * Note that perception time is assumed to be $1\frac{1}{2}$ seconds.

†Reference citations are shown on page 220.

CONTENT OUTLINE

b. Coefficient of friction (f)

TEACHING POINTS AND TECHNIQUES

* Explain that f varies with speed and is influenced by;

1. Type of tire
2. Air pressure
3. Amount of tire tread
4. Type and condition of pavement
5. Presence of mud, snow, water, or ice on the pavement
6. Temperature
7. Vehicle load and weight
8. Brake fade

* Point out that the coefficient of friction for wet pavements is used for design criteria, noting that only 80 to 93 percent of the design speed is used. (Ref. B, pp. 136 - 138)

Design Speed	Actual Speed	f
30	28	0.36
40	36	0.33
50	44	0.31
60	52	0.30
65	55	0.30
70	58	0.29
75	61	0.28
80	64	0.27

* Indicate that most classification charts do not list the 65, 75, and 80-m.p.h. speed increments.

* Point out that the design speeds of 75 and 80 m.p.h. are applicable only to highways with full control of access. (Ref. B, p. 136)

* State that the coefficients of friction for a dry pavement are about twice those for a wet pavement.

* Note also that trucks require a longer stopping distance but this is offset because of better driver visibility and slower traveling speeds.

22536

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
4. Application	* Find the stopping distance on a wet pavement when the design speed is 60 m.p.h. (actual speed 52 m.p.h.). * Recall that the perception time and brake reaction time is assumed to be a total of $2\frac{1}{2}$ seconds. 60 m.p.h. = 88 ft./sec. $\frac{52}{60}$ x 88 ft./sec. = 76 ft./sec. 76 ft./sec. x 2.5 sec. = 191 ft. $d = \frac{V^2}{30f}$ $= \frac{52 \times 52}{30 \times 0.30}$ = 300 ft. * State that the stopping distance of the vehicle is 191 ft. plus 300 ft. for a total of 491 ft. This is rounded off to 475 ft. for design purposes.
5. Design Criteria	* Indicate that the safe stopping sight distances, rounded for design, are as follows: 1. 200 ft. at 30 m.p.h. 2. 275 ft. at 40 m.p.h. 3. 350 ft. at 50 m.p.h. 4. 475 ft. at 60 m.p.h. 5. 550 ft. at 65 m.p.h. 6. 600 ft. at 70 m.p.h. 7. 675 ft. at 75 m.p.h. 8. 750 ft. at 80 m.p.h.
B. Minimum stopping sight distance on grades	* Explain the effect of a grade on the stopping ability of a vehicle. * Note that the percent of grade divided by 100 (g) is added on a plus grade (and subtracted on a minus grade) to f in the denominator of the formula for braking distance.

22537

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Point out that factors which affect this time include: 1. Distance to the object 2. Driver alertness 3. Optical ability of the driver 4. Visibility 5. Type and condition of pavement 6. Color of object 7. Speed (people are usually more alert at high speeds)
2. Brake reaction time	* Mention that the time lapse from the instant a driver realizes he must stop to the instant the brakes are applied is called brake reaction time. * State that the average brake reaction time is about $\frac{1}{2}$ second and to provide a factor of safety another $\frac{1}{2}$ second is added. Thus the brake reaction time is assumed to be 1 second.
3. Braking distance	* Indicate that the distance required to stop a vehicle after the brakes are applied is called braking distance * Note that braking distance depends directly on tires, brakes, roadway, grade, and speed. (Ref. B, pp. 136-138)
a. Formula	* State that the braking distance is determined by a formula utilizing the coefficient of friction between the tires and the roadway (Ref. A, pp. 155-157; Ref. B, p. 136): $$d = \frac{V^2}{30f}$$ where d = braking distance in feet V = speed in miles per hour f = coefficient of friction between tires and roadway

22524

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

(1) Derivation of factor

* Explain how the factor 30 is determined.

* Recall that force times distance equals change in kinetic energy.

$$Wfd = \frac{Mv^2}{2} = \left(\frac{1}{2}\right)\left(\frac{W}{g}\right)v^2 = \frac{Mv^2}{2}$$

where W = weight in pounds
f = coefficient of friction (no units)
d = distance in feet
M = mass in foot-pounds/second /second or $\frac{W}{g}$
v = velocity in feet/second
g = acceleration due to gravity or 32.2 feet/second/second

* Divide both sides of the equation by W and f:

$$d = \frac{v^2}{2gf}$$

* Indicate that it is desirable to eliminate g (a constant) and to use V in terms of miles per hour instead of feet per second. This is done as follows:

$$V \text{ (miles per hour)} \times \frac{5280 \text{ feet/mile}}{3600 \text{ seconds/hour}}$$

* Note that v is squared in the formula, and since the acceleration due to gravity remains quite constant at 32.2 feet/second/second, the mathematical manipulation may be simplified by incorporating these facts as follows:

$$\frac{V^2 \times \frac{(5280)^2}{(3600)^2}}{32.2 \text{ ft./sec./sec.}}$$

Simplified the above expression becomes:

$$\frac{V^2}{15}$$

Substituting this factor into the formula $d = \frac{v^2}{2gf}$ it now becomes:

$$d = \frac{V^2}{30f}$$

22535

MICROCOPY RESOLUTIO
NATIONAL BUREAU OF STA

UNIT VII (14.0901-08)

RECORD MANAGEMENT

Performance Objectives:

Upon completion of this unit the student will be able, in a simulated situation, to demonstrate her knowledge of filing procedures by organizing material for a filing system. She will be able to score at least 80% on an instructor made test dealing with rules and routines for filing.

Unit Outline:

A. Need for Filing

1. Information retrieval

2. Safe keeping

3. Storage

B. Types of Business Papers and Records Commonly Filed

1. Office

2. School

3. Home

C. Filing Equipment and Supplies

D. Alphabetic Filing

1. Advantages and disadvantages

2. Rules for indexing and filing

E. Filing Procedures

1. Checking for release mark

2. Reading to determine content

3. Indexing

4. Coding

5. Cross-referencing

6. Sorting

N TEST CHART
ANDARDS-1963-A

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Discuss the relation of design speed to sight distances required for stopped vehicles at intersections along a major highway. (Ref. B, p. 398)
	* Note that the minimum sight distance at a controlled intersection is greater than the product of the design speed of the major highway and the time necessary for the stopped vehicle to start and cross the road.
	* Explain the variables influencing perception time and the acceleration of the vehicle.
3. Effect of skew	* Sketch two highways intersecting at less than a right angle and show how this alters the line of vision.
	* Add that the actual line of sight is relatively unimportant as long as the sight triangle is free of obstructions.
	* Mention that this is true because the driver in the obtuse angle quadrant can see the full sight triangle with no effort since the angle between the sight line and any other vehicle is small. But the driver in the acute angle quadrant must struggle to see the full sight triangle area.
F. Effect of grade	* State that all discussions about minimum sight distance at intersections are based on level highways.
	* Indicate that grades up to 3 percent do not materially affect stopping sight distances but it is better to limit the grade of the intersecting leg to 3 percent
II. Lane Width	* Mention that all designations of lane width are based on safety. Note that lane width is directly related to the average annual daily traffic (A.A.D.T.) and to the design hour volume (DHV) of traffic. (Ref. A, pp. 132-135; B, pp. 225-227; Ref. C, section 22, p. 24)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Effects	* Discuss the bad psychological effect on the driver when there is little or no lateral clearance from an obstruction, or when passing vehicles have little allotted space in which to maneuver. * Point out that at the present time the maximum allowable width of vehicles is $8\frac{1}{2}$ ft. in most states and that this width is used for design purposes.
B. Clearances	* Mention that a vehicle should have a minimum of $1\frac{1}{2}$-ft. clearance to the centerline and a 1-ft. edge clearance whenever shoulders are used. Whenever curbs are used this edge clearance is increased to 3 ft.
C. Vehicle size	* State that a maximum sized vehicle requires a lane 11 ft. wide or when curbs are used a lane 13 ft. wide.
D. Cost	* Note that the extra cost of wider lanes is offset to a great extent by the reduction in cost of surface maintenance due to reduced wheel concentrations at the edges of the pavement slab. (Ref. B, p. 225)
E. Safety	* Indicate that in the interest of safety, efficiency, and ease of operation lane widths of 11 to 13 ft. are desirable on any highway. * Compare the lane widths with respect to traffic counts as shown on the geometric standards sheet. (Ref. D)

QUESTIONS FOR REVIEW

1. Explain sight distance as used in highway design.
2. What increments of time are involved in the computation of minimum stopping sight distances?
3. Name five factors which can drastically affect the perception time of an individual driver.

4. List eight conditions which will influence the braking distance of a vehicle.

5. What component distances are actually involved in the computation of the minimum passing sight distance?

6. What is the minimum passing sight distance for a design speed of 60 m.p.h.?

7. Explain the minimum sight triangle.

8. How does the skew angle affect sight distance at an intersection?

ASSIGNMENT

1. Read pages 135-143 in Ref. A, and pages 222-240 in Ref. B.

2. Compute the minimum stopping sight distance for design speeds of 30, 40, 50, 70 and 80 m.p.h.

INSTRUCTOR'S NOTES

22544

Lesson 5 - Features of Design

OBJECTIVES

- To provide a description of functional design with respect to various geometric features
- To set the basis for design criteria

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Curbs	* Describe the curb as a geometric feature that affects the safety and utility of a highway. (Ref. A, p. 138; Ref. B, pp. 227-234, 256)†
A. Uses	* Discuss the following uses of curbs: 1. Controls drainage 2. Confines vehicles in a designated path 3. Delineates the pavement or median edge 4. Assists in the development of the roadside
B. Types	* Draw sketches on the chalkboard comparable to those in Ref. B, pages 228 and 232, and describe curbs as either barrier type or mountable type. (Ref. C, section 22, pp. 20-22)
1. Barrier type	* Point out that the barrier type is used to prevent vehicles from leaving the pavement and that a 6-in. vertical faced curb is considered to be a barrier or nonmountable type. * Note that the barrier type has disadvantages since it prevents police cars, ambulances, and tow trucks from crossing over to an opposite lane.
2. Mountable	* Mention that the mountable barrier allows vehicles to cross over and, technically, only delineates the pavement edge.

†Reference citations are shown on page 220.

22545

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
II. Medians	* Define the median as a dividing strip separating opposing traffic on a highway. (Ref. B, pp. 251-256; Ref. L, pp. 36-38)
A. Uses	* List the uses of the median (Ref. A, p. 134; Ref. C, section 22, pp. 19-22): 1. Separates opposing traffic 2. Minimizes headlight glare 3. Provides waiting space for crossing or turning vehicles at grade intersections 4. Provides a storage area in case of emergency 5. Affords an opportunity to design line and grade to fit the topography
B. General features	* Indicate that the median must be highly visible during the day and night. * Mention that medians are built from 4 to 80 ft. wide and note that: 1. A median less than 4 ft. wide is defined as a separator. 2. A median less than 8 ft. wide is usually paved. 3. A high barrier median requires added edge clearance. * State that a driver feels better psychologically when the median is at least 40 ft. wide. A median is sometimes called a mall when over 40 ft. wide. * Point out that a highway looks attractive when the median is over 60 ft. wide.
C. Cross section	* Note that when a median is wide enough to be turfed, it is depressed to help drainage. This is especially true in heavy snow areas.

22546

CONTENT OUTLINE

D. Widths

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	chalkboard, showing an intersection utilizing a major and a minor road.
	* Discuss the space-time-velocity relationship between two vehicles entering the intersection.
2. Types of intersections	* Note that ordinary intersections are classified into three types.
a. Not controlled and vehicle speed altered	* Describe the first type of intersection as one not controlled by signs or signals and where the operator approaching the intersection must see a hazard early enough to alter the speed of his vehicle to avoid collision.
	* Show that in this case the minimum sight distance is the hypotenuse of the sight triangle when each leg of the triangle represents the distance traveled in 3 seconds by two vehicles entering the intersection. Emphasize that this sight distance is a minimum and not a desirable one.
b. Not controlled and vehicle stopped	* Describe the second type of intersection as one not controlled by signs or signals and where the operator of either vehicle approaching the intersection must be able to see both the intersection and the intersecting highway early enough to stop his vehicle if necessary.
	* Compute the minimum sight triangle, utilizing the safe stopping sight distances of the two vehicles entering an intersection of a major highway with a design speed of 60 m.p.h. and a minor road with a design speed of 50 m.p.h.
c. Controlled	* Describe the third type of intersection as one controlled by stop signs on the minor road and where a driver of the stopped vehicle should see enough of the major highway to be able to cross it before an approaching vehicle reaches the intersection.

22541

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

NORMAL CROSS-SECTION

FIGURE I

* Add that low surface types are built less accurately and with coarser top materials which tend to retard the flow of water.

2. Parabolic crown

* Describe the parabolic crown as having a slightly rounded surface at the center and an increasing cross slope toward the pavement edge.

* State that the points used to plot the curvature of this crown are determined by the following equation:

$$x = \frac{4cy^2}{w^2}$$

where x = vertical distance in inches from theoretical gradeline to any point on parabola

c = total crown in inches

y = horizontal distance in feet of any point on parabola from centerline

w = width of cross section in feet

22554

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Sketch figure 2 on the chalkboard and point out the elements of a parabolic crown.

PARABOLIC CROWN
FIGURE 2

a. Application

* Find the difference in elevation between the theoretical gradeline and points 5 ft. apart on a 40-ft. cross section which is to be crowned 5 in.

* Use the equation to show that the difference in elevation 5 ft. from the center is $\frac{5}{16}$ in.

$$x = \frac{4cy^2}{w^2}$$

$$x = \frac{4 \cdot 5 \cdot 25}{1600}$$

$$x = \frac{500}{1600}$$

$$x = \frac{5}{16} \text{ in.}$$

* Solve for the remaining points and indicate that they are:

$1\frac{1}{4}$ in. at 10 ft.

22555

7. Filing

8. Out-slip

9. Follow-up

F. Other Filing Systems

Supplemental Teaching Aids:

Good resource people for this unit are school librarians or bank employees. A visit to a local library to observe its filing system is useful also.

The following are good resource books for the unit; Business Filing and Records Control, 3rd ed., Ernest D. Bassett, South-Western, Cincinnati, 1963, Records Management, Mary C. Griffin, Allyn and Bacon, Boston, 1964, and Gregg Quick Filing Practice, McGraw-Hill, New York, 1965.

A useful programmed instruction book is Basic Rules of Alphabetic Filing, by Fahrner and Gibbs, South-Western, Cincinnati, 1965. Free or inexpensive pamphlets are available from Smead Manufacturing Co., Hastings, Minnesota (Do's & Dont's of Filing and Science of Filing) and from the Oxford Filing Supply Company, Inc., Garden City, N. Y. 11533 (33 Common Filing Questions). Remington Rand, Systems Division has the film "It Must be Somewhere", while Cornet Films has "Filing Procedures in Business".

Training Time 15-20 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	$2\frac{13}{16}$ in. at 15 ft.
	5 in. at 20 ft.
D. Control of cross slope	* Indicate that the amount of crowning is controlled by the rollover effect, climate, and vehicle design.
1. Rollover effect	* Define rollover effect as the algebraic difference between cross slopes.
	* Explain that a vehicle in passing maneuvers must cross and recross the crown line and negotiate a rollover of $\frac{1}{2}$ in. per foot or 4 percent when the normal crown section is $\frac{1}{4}$ in. per foot.
	* Note that this is dangerous on a high speed road and that heavy trucks will sway from side to side, making steering difficult.
2. Climate	* Point out that a lesser slope is used in northern areas where snow and ice conditions are prevalent.
3. Vehicle design	* State that vehicles are built with a symmetrical caster-camber arrangement for level pavements and there is no difficulty in steering until the cross slope exceeds $\frac{1}{4}$ in. per foot.
VI. Shoulders	* Define the shoulder as a contiguous portion of the roadway built for stopped vehicles, emergency use, and lateral support of the pavement. (Ref. B, pp. 234-241)
A. Width of shoulder	* Add that the shoulder width varies from zero to 12 ft.
	* Mention that the width of the shoulder is directly related to: 1. Type of highway 2. Traffic volume 3. Traffic speed

22556

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	4. Traffic composition 5. Type of terrain
	* Review the shoulder criteria as listed in the classification chart. (Ref. D)
B. Advantages	* Discuss the following advantages of a shoulder: 1. Provides space for emergency stops 2. Provides space for rest stops, map reading, etc. 3. Provides space for escape from a potential accident 4. Provides a psychological sense of freedom 5. Assists sight distance in cut sections 6. Provides aesthetic improvement 7. Increases traffic capacity 8. Encourages uniform speed 9. Provides space for maintenance and snow removal 10. Provides lateral clearance for signs, guide rails, delineators, etc. 11. Allows storm water to be drained farther away from the pavement minimizing edge seepage 12. Affords structural support to the pavement
C. Cross section	* Sketch on the chalkboard the cross section of the shoulder with the standard slope of 1 in. per foot, down and away, from the edge of pavement.

22557

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Note that as a vehicle speeds around a curve, it has tremendous centrifugal force and the vehicle remains on a level road only by an equal centripetal force. This centripetal force can come only from the force of friction between the tires and the weight of the vehicle.

* Sketch on the chalkboard the forces acting on and caused by the vehicle shown in figure 3.

* State that W is the pull of gravity and P is the upward push on the vehicle by the pavement.

VEHICLE AND PAVEMENT FORCES

FIGURE 3

CONTENT OUTLINE

4. Unequal forces

TEACHING POINTS AND TECHNIQUES

* Indicate that when the centrifugal and centripetal forces are not equal, circular motion does not exist.

* Sketch figure 4 on the chalkboard and explain that when the centripetal force is insufficient to hold the vehicle on the road, centrifugal force causes the vehicle to move on a tangent to the curve as it attempts to follow a straight line.

* Elicit other examples of these forces and call attention to the fact that centripetal force holds us on earth.

PATH OF VEHICLE WHEN CENTRIPETAL FORCE IS LESS THAN CENTRIFUGAL FORCE

FIGURE 4

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

5. The equation of force

* Point out that Newton's second law can be equated as force equals mass times acceleration.

$$F = Ma$$

* Note that mass is equal to the weight divided by the force of gravity.

$$M = \frac{W}{g}$$

* Indicate that acceleration in circular motion is equal to the velocity squared, divided by the radius.

$$F = Ma = \frac{(W)(V^2)}{(g)(r)}$$

a. Application

* Find the centrifugal force acting on a 4000-lb. vehicle traveling at 60 m.p.h. (88 ft. per second) traveling around a curve of a 1000-ft. radius.

$$F = Ma$$

$$= \frac{(W)(V^2)}{(g)(r)}$$

$$= \frac{4000 \text{ lbs.}}{32 \text{ ft./sec./sec.}} \times \frac{(88 \text{ ft./sec.})^2}{1000 \text{ ft.}}$$

$$= 968 \text{ lbs.}$$

* State that 968 lbs. of centrifugal force are acting outwardly against the forces of friction and gravity of the vehicle and that 968 lbs. of centripetal force are acting inwardly on the vehicle, attempting to accelerate it into the center of curvature.

C. Banking of curves

* Add that when a vehicle rounds a curve at constant speed, it is accelerating toward the center of the curve.

* Point out that on a highway that is level transversely, the only force holding a car on the pavement is the small and uncertain force of friction. The pavement is, therefore, banked or

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

tilted to assist the vehicle to remain in curvilinear motion.

* Sketch on the chalkboard figure 5. Explain the pull of gravity (W) and the push (P) exerted by the road and normal to it that act on a vehicle rounding a curve, banked at an angle theta.

VEHICLE ON A BANKED CURVE

FIGURE 5

PARALLELOGRAM OF FORCES

FIGURE 6

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
C. Low type	* State that the low type surface can range from surface treated earth roads to ordinary dirt roads.
V. Crowns	* Define the crown as the transverse slope (cross slope) of a pavement. (Ref. A, pp. 135-137; Ref. B, pp. 223-225)
A. Need	* Mention that the chief reason for crowning a pavement is to provide for removal of surface water as quickly as possible.
B. Type of cross slope	* Describe the normal cross slope (N.C.S.) as two plane surfaces meeting at the crown or high point. * Draw a simple sketch on the chalkboard of a typical cross section. * Indicate that most city streets are usually crowned parabolically.
C. Amount of cross slope	* Point out that a slope of $\frac{3}{16}$ in. per foot was previously used for crowning a concrete pavement and $\frac{1}{4}$ in. per foot for a bituminous pavement, but a recent change calls for a $\frac{1}{4}$ in. per foot cross slope for all pavements regardless of the surface.
1. Plane crown	* Indicate that with a plane crown there is a uniform slope on each side extending from the center to the edge of the pavement. * Note the difference in elevation between the crown and the edges of the pavement on the 24-ft. cross section shown in figure 1 on page 44. * Emphasize that in general the lower the surface type, the greater the cross slope since lower type roads are designed for lower speed and fewer trucks.

22553

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
D. Stability	* Note that the shoulder must support vehicle loads in all types of weather. In the case of ordinary shoulders, the material should be granular, treated, and compacted. (Ref. C, Section 22, p. 39) * Describe the bituminous stabilized shoulders now being used. Add that too good a shoulder invites usage as another driving lane unless it is color contrasted or jiggled-barred.

QUESTIONS FOR REVIEW

1. Why are all curbs not constructed as a barrier type?
2. What is the value of a 14-ft. median on a city arterial?
3. Name three types of pavement surfaces.
4. Why is a graveled road cross sloped at $\frac{1}{2}$ in. per foot?
5. What is the normal cross slope of a bituminous surfaced highway?
6. Why would a parabolic crown be troublesome on a wide pavement?
7. Is there a connection between a low automobile and rollover effect?
8. Name five factors which control the width of a shoulder.
9. List 10 uses of the shoulder.
10. What is the usual cross slope of a standard shoulder?
11. How does climate affect the amount of cross slope used on a pavement?
12. What is the purpose of guide railing?
13. List five factors which would mandate the use of guide railing.
14. Describe three types of guide railing.

ASSIGNMENT

1. Solve problems 5-1 through 5-4 on page 187 in Ref. A.
2. Read pages 144-146 in Ref. A and pages 153-157 in Ref. B.

Lesson 6 - Horizontal Alinement (Control of Curvature)

OBJECTIVES

- To provide a background of pertinent information relating to the control of horizontal curvature
- To introduce superelevation as a limiting control of curvature

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Balanced Design	* State that an essential requirement in highway design is the balance of all geometric elements. This provides safe operation at the speed allowed by the general condition of the highway. (Ref. B, p. 152)†
A. Design speed	* Note that design speed is used as the overall control in achieving this balance of geometric elements.
B. Highway curves	* Point out that in the design of highway curves it is necessary to establish the proper relationship between design speed and curvature and their joint relationship with superelevation.
II. Mechanics of Curvature	* State that the relationship between speed and curvature is a matter of mechanics which explain the forces acting on a body in motion.
A. Newton's first law of motion	* Explain Newton's first law of motion—that a body at constant speed will move in a straight line until a force is applied to it. * Use as an example a baseball thrown in the air.
B. Newton's second law of motion	* Explain Newton's second law of motion—that a force acting on a body will accelerate that body in the direction of the force.

†Reference citations are shown on page 220.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Centrifugal force	* Point out that whenever a body is traveling around a circular curve at constant speed, the moving body acts on its restraining agent with a constant force directed radially outward from the center. * Use as an example a stone on a string (the restraining agent) whirled in a circle, or a bucket of water swinging rapidly in a circle over one's head.
2. Centripetal force	* State that centripetal force is that force which acts on the moving body by the restraining agent. * Note that the centripetal force acting on a body moving in a circular path varies directly as the square of the speed and inversely as the radius of the circle. Thus if the speed of a vehicle on a curved surface is doubled, four times as much centripetal force is brought into play.
3. Equal forces (equilibrium)	* Indicate that a body is in equilibrium when the forces acting upon it are so arranged that the body does not accelerate or decelerate. * Add that for uniform circular motion centrifugal and centripetal forces are always equal in magnitude and opposite in direction but they cannot balance each other since they are not acting upon the same object. * Repeat the example of the stone and string. The string pulls the stone, causing it to follow a definite path (a circle) so that centripetal force accelerates the stone toward the center of the circle. * Explain that a vehicle traveling on a curved surface acts the same as any body in motion on a circular path.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	3. Type of area (urban or rural)
	4. Frequency of slow moving traffic (uncertain operation
B. Minimum safe radius	* State that the maximum degree of curvature or the minimum radius is a limiting value for a given design speed and it is determined only when the maximum superelevation rate and the safe side friction factor have been established. (Ref. A, p. 146; Ref. E, pp. 5-6)
1. Application	* Utilize the information provided in the problem, found on page 53, and find the minimum safe radius using 0.08 ft./ft. as the maximum superelevation rate and a design speed of 60 m.p.h.

* Use the empirical equation:

$$e + f = \frac{V^2}{15r}$$

and solve for r:

$$r = \frac{V^2}{15(e + f)}$$

$$= \frac{(60)(60)}{15(0.08 + 0.13)}$$

$$= \frac{3600}{3.15}$$

$$= 1143 \text{ ft.}$$

* Note that the problem used a 1000-ft. radius which actually is too sharp. The maximum degree of curvature which can be used under the conditions of the problem is 5°.

* Find the minimum safe radius for an arterial highway with a superelevation rate of 0.06 ft./ft. and a design speed of 40 m.p.h.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

$$r = \frac{V^2}{15(e + f)}$$

$$= \frac{(40)(40)}{15(0.06 + 0.15)}$$

$$= \frac{1600}{3.15}$$

$$= 508 \text{ ft.}$$

* Find the minimum safe radius for a rural highway with a superelevation rate of 0.08 ft./ft. and a design speed of 80 m.p.h.

$$r = \frac{V^2}{15(e + f)}$$

$$= \frac{(80)(80)}{15(0.08 + 0.11)}$$

$$= \frac{6400}{2.85}$$

$$= 2246 \text{ ft.}$$

QUESTIONS FOR REVIEW

1. What is the relationship between Newton's laws of motion and curvilinear design?

2. What is centrifugal force?

3. What is centripetal force?

4. If a centrifugal force is in equilibrum with a centripetal force, why do they not balance each other?

5. In banking what is the relationship between "e" and the tangent of the banking angle?

6. How does side friction enable a vehicle to travel at a slower or faster rate than the design speed on a banked curve?

7. What is the side friction factor for a design speed of 50 m.p.h?

8. Why does New York State limit the maximum superelevation to 0.08 ft. per foot.

22573

9. Describe the control afforded by the minimum safe radius.

10. How does a motorcycle ride in a horizontal position on a race track?

ASSIGNMENT

1. Study pages 146-151 in Ref. A, and pages 157-181 in Ref. B.

2. Find the amount of centrifugal force that is exerted by a 30-ton semi-trailer traveling at 70 m.p.h. around a 3°-curve on a rural highway?

3. Find the amount of banking necessary to furnish enough centripetal force to hold the truck on a 12-ft. pavement without the force of friction.

4. Find the banking necessary when the force of friction is used.

5. What should the minimum safe radius be for this situation?

INSTRUCTOR'S NOTES

Lesson 7 - Horizontal Alinement (Superelevation Runoff)

OBJECTIVES

- To furnish a practical application of the mechanics of superelevation
- To discuss the methods used in achieving full bank

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Superelevation Standards	* Point out that in establishing standards of superelevation, the minimum curvature should vary with the range of speeds.
A. Flat curve	* Mention that the pavement of a flat curve requires no banking or superelevating. (Ref. B, p. 162)†
	* Note that a vehicle entering a curve to the right has some superelevation because of the normal cross slope. Traffic entering a curve to the left has an adverse or negative superelevation because of the normal cross slope.
	* State that the resultant friction required to counteract both centrifugal force and negative superelevation is small.
B. Limit of friction factor	* Indicate that as the curve becomes sharper the friction factor is not sufficient to hold the vehicle on the highway and superelevation is required.
	* Add that the minimum curvature for which superelevation is required or the maximum curvature for which a crowned pavement cross section is appropriate is part of any standard for superelevation.
C. Superelevation rates	* Explain that in highway curve design it is necessary to determine superele-

†Reference citations are shown on page 220.

22575

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	vation rates for the range of curvature used for each design speed. (Ref. B, p. 157)
1. Extremes of superelevation	* Point out that the extremes of superelevation range from zero on a tangent highway to a maximum, established by practical considerations like ice and snow. This maximum superelevation is used to determine the maximum curvature for each speed.
2. Area between extremes	* Emphasize that for radii of curves falling between zero and maximum curvature for a given design speed, the superelevation should be distributed so there is a logical relationship between the side friction factor and the superelevation rate.
	* State that there is a curvilinear relationship between the degree of curve and the varying superelevation rate.
	* Note that this curve is parabolic.
3. Graphs	* Discuss the graphs on pages 163-166 of Ref. B, which show a superelevation rate relationship between each design speed and the degree of curvature.
	* Mention that the four graphs are based on the maximum superelevation rates (established by practical considerations) of 0.06, 0.08, 0.10 and 0.12.
II. Superelevation Runoff	* Describe superelevation runoff as a general term denoting the length of highway needed to accomplish the change in cross slope of the pavement from a normal crown section to a fully superelevated section or vice versa. (Ref. B, p. 174; Ref. E, pp. 6-7)
	* Note that this transition is one of the most important features in highway design. It must be accomplished with no appreciable loss in speed and with the safety and comfort of the occupants of the vehicle assured.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* State that the forces P and W must be so proportioned that their resultant F is horizontal, since this is the centripetal force (the force of friction between tires and pavement) required to achieve circular motion around a horizontal curve. (Ref. E, p. 4)

* Draw figure 6 (found on page 54) on the chalkboard and note that the angle theta (Θ) in figure 5 is equal to angle theta in figure 6. Explain in the parallelogram of forces the following:

$$\tan \Theta = \frac{F}{W}$$

since $F = Ma$

$$\tan \Theta = \frac{Ma}{W}$$

since $M = \frac{W}{g}$

$$\tan \Theta = \frac{(W)(a)}{(g)(W)}$$

but $a = \frac{v^2}{r}$

$$\tan \Theta = \frac{(W)(v^2)}{(g)(W)(r)}$$

$$= \frac{v^2}{(g)(r)}$$

where v = speed of vehicle in feet per second

g = acceleration due to gravity of 32 ft. per sec. per sec.

r = radius of curve in feet

* Describe the banking angle as that angle whose tangent is equal to v squared, divided by g times r.

22565

VIII (14.0901-06)

SOURCES OF INFORMATION

Performance Objectives:

Upon completion of this unit the student will be able to demonstrate her knowledge of information sources by compiling a list of information to meet specifications designated by the instructor.

Unit Outline:

A. Reference Books as a Tool of the Office Worker

1. Importance of accurate business information
2. Kinds of information needed
3. Necessity of obtaining information quickly
4. Necessity for initiative in finding information

B. Reference Books of the Office Worker

1. Dictionaries
2. Reference manual for stenographers and typists
3. English grammar and style books
4. Directories
5. Thesaurus

C. Other Sources of Factual Information

Supplemental Teaching Aids:

The most obvious resource person is of course the librarian. Also available is the Gregg Secretarial Record #6, Set #2 Finding Needed Information. The film "Look It Up-Dictionary Habits" (11 min.) is available from Cornet Instructional Films.

Training Time 3-5 hours

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

$$\Theta = \tan^{-1} \frac{v^2}{(g)(r)}$$

* Mention that the expression banking is usually termed superelevating.

1. Application

* Use the facts that are given for the problem found on page 53, and compute the banking required so that the developed centripetal force will hold the vehicle in its circular path without depending on friction.

* Reiterate that the

$$\tan \Theta = \frac{v^2}{(g)(r)}$$

$$= \frac{(88 \text{ ft./sec.})(88 \text{ ft./sec.})}{(32 \text{ ft./sec./sec.})(1000 \text{ ft.})}$$

$$= 0.242$$

* Note that all units cancel out, leaving a unitless answer which is the slope of the hypotenuse in the triangle where the tangent of Θ is equal to the side opposite over the side adjacent.

* Explain that this means that the vehicle in the problem requires a cross slope of 0.242 ft. per foot to achieve this particular circular motion without resorting to the force of friction between the tires and the pavement.

* State that the 0.242 ft. per foot or 0.242 in. per inch or 0.242 yd. per yard is equal to about 3 in. per foot or in a 12-ft. lane about 3 ft. of bank.

* Sketch figure 7 on the chalkboard and review the mechanics of the problem. (Found on page 57)

22566

CONTENT OUTLINE TEACHING POINTS AND TECHNIQUES

AMOUNT OF BANKING REQUIRED

FIGURE 7

a. Empirical formula

* Indicate that the required banking can also be determined by using the following empirical formula:

$$e = \frac{V^2}{15r}$$

where V is measured in miles per hour
r is measured in feet

(1) Derivation of factor

* Show the derivation of the factor 15.

* Recall the formula for determining the required banking as:

$$\tan \Theta = \frac{v^2}{(g)(r)}$$

where v is measured in feet per second
g is measured in feet per second per second
r is measured in feet

* Point out that tan Θ equals e.

22567

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Indicate that to simplify the mathematical calculation it is desirable to eliminate g (a constant) and use v in terms of miles per hour instead of feet per second. This is done as follows:

$$V(\text{miles per hour}) \times \frac{5{,}200 \text{ ft./mi.}}{3600 \text{ sec./hr.}}$$

Since v is squared in the formula the relation becomes:

$$\frac{V \times 5280}{3600} \times \frac{V \times 5280}{3600} \quad \text{or}$$

$$V^2 \times \frac{5280^2}{3600^2}$$

Since the acceleration due to gravity remains quite constant at 32.2 ft. per second per second the calculation may be simplified by incorporating this fact in the above transformation as follows:

$$\frac{V^2 \times \frac{5280^2}{3600^2}}{32.2}$$

Simplified the above expression becomes:

$$\frac{V^2}{15}$$

Substitute this expression into the original formula:

$$\tan \Theta = e = \frac{V^2}{15}$$

where V is measured in miles per hour
r is measured in feet

* Recompute the problem using the empirical formula:

$$e = \frac{(60)(60)}{(15)(1000)}$$

$$= 0.24$$

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Compare this amount of banking to a racetrack and state that in this case friction does no work.
	* Indicate that the vehicle will follow its circular path only when it is traveling at a constant speed which in this case is precisely 60 m.p.h.
2. Flaws in banking	* Caution that severe banking will force a slow driver to steer up the cross slope, or against the direction of the curve.
	* Add that if a car is traveling faster than the design speed, only tire friction will prevent the vehicle from sliding to the outside.
	* Conclude that highway banking must therefore depend on the force of friction.
III. The Force of Friction	* Establish that the force of friction is always present during unideal conditions (most of the time). (Ref. B, pp. 152-153)
A. Coefficient of friction	* Call this force the side friction factor. It manifests itself as a coefficient of friction.
	* Elaborate on the different terms assigned to side friction, such as "lateral ratio," "cornering ratio," "friction factor," "unbalanced centrifugal ratio, "and "unbalanced side friction." (Ref. B, p. 153)
	* Recall that the coefficient of friction is equal to the force of friction divided by the vehicle weight component perpendicular to the pavement (a unitless number).
	* Emphasize that the coefficient of friction is completely independent of the contact area involved.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Add that since the coefficient of friction diminishes the amount of banking, the formula now reads: $e + f = \frac{V^2}{15r}$
B. Side friction factors	* List the commonly used coefficients or side friction factors for the eight design speeds used at present. (Ref. B, p. 158) 1. 30 m.p.h. at 0.16 2. 40 m.p.h. at 0.15 3. 50 m.p.h. at 0.14 4. 60 m.p.h. at 0.13 5. 65 m.p.h. at 0.13 6. 70 m.p.h. at 0.12 7. 75 m.p.h. at 0.11 8. 80 m.p.h. at 0.11 * Emphasize that these factors are not the maximum values and a safety factor has to be considered.
C. Application	
1. Without friction	* Recompute the problem empirically without using the coefficient of friction. $e = \frac{V^2}{15r}$ $= \frac{(60)(60)}{(15)(1000)}$ $= 0.24$ ft./ft.
2. With friction	* Recompute the problem empirically using the coefficient of friction. $e + f = \frac{V^2}{15r}$ $= 0.24$ ft./ft. $e = 0.24$ ft./ft. $- f$ $= 0.24 - 0.13$ $= 0.11$ ft./ft.

22570

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Indicate that friction reduces the banking required for a 12-ft. pavement from 2.88 ft. to 1.32 ft.
IV. Superelevation	* Describe superelevation as an expression for banking and list the commonly used maximum rates as 0.06 ft./ft., 0.08 ft./ft., 0.10 ft./ft., and 0.12 ft./ft. (Ref. A, pp. 146-151; Ref. B, pp. 155-156)
	* Emphasize that using too high a maximum rate for superelevation creates a hazard in any area having ice and snow conditions.
	* Indicate that in New York State the allowable maximum rate of superelevation is 0.08 ft./ft. for rural highways, 0.06 ft./ft. for urban highways and 0.063 ft./ft. for structures.
	* Point out that consideration of superelevation has been a weak point in highway design but now considerable emphasis is being placed on this element.
V. Control of Curvature	* Caution that the maximum curvature for a given design speed is determined by the combination of the maximum rate of superelevation and the factor for safe side friction. (Ref. B, pp. 155-157)
	* Note that the limitations of the maximum superelevation rate and the safe side friction factor are technically the most important control in the design of curvature.
A. Control of rates	* Explain that the maximum superelevation rates are controlled by: 1. Climatic conditions (frequency of snow and ice) 2. Terrain conditions (flat or mountainous)

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Explain the three ways of attaining superelevation. (Ref. A, pp. 146-151; Ref. B, pp. 178-181)

1. Revolving the pavement about the centerline profile

2. Revolving the pavement about the inside edge profile

3. Revolving the pavement about the outside edge profile

* State that for simplicity the curve in all problems and sketches will always be to the right.

A. Revolving pavement about centerline profile

* Draw figure 8 on the chalkboard which shows the first method. Use colored chalk for each position of the pavement and exaggerate the vehicle scale.

ATTAINMENT OF SUPERELEVATION BY REVOLVING ABOUT CENTERLINE

SEPARATE VIEWS

FIGURE 8

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

ATTAINMENT OF SUPERELEVATION BY REVOLVING ABOUT OUTSIDE EDGES

FIGURE 14

* Caution that to use this pivot on a four-lane divided highway the median must be at least 30 ft. wide to handle the difference in elevation between the median edges.

* State that if the median is over 40 ft. wide, the roadways may be treated as separate highways.

III. Placement of Superelevation

* Review briefly the geometry of the simple curve. Note that when a vehicle traveling on a tangent, reaches the point of curvature (P.C.) of a curve, the natural tendency for it to continue straight on must be overcome.

* Explain that superelevation runoff helps the vehicle move from a tangent direction to a curvilinear direction.

CONTENT OUTLINE | TEACHING POINTS AND TECHNIQUES

Schemetically, this takes place at the P.C. of the curve, but actually this point must be drawn out for a reasonable distance because of physical requirements.

A. Action of vehicle

* Display the sketches showing the method of pivoting a pavement about the centerline profile and describe the action when vehicles approach the curve, drive the curve, and leave the curve.

B. Superelevation on the tangent

* Point out that while a vehicle on the tangent is driving in a slightly unnatural position it would be in an exceedingly unnatural position if the pavement revolved from positions 1 through 4 completely on the tangent. Here full bank would be coincident with the P.C. in order to satisfy the laws of mechanics.

C. Superelevation on the curve

* Add that if the vehicle reaches the P.C. on a normal cross slope and is then gradually superelevated on the curve, it will be in opposition to the mechanics of curvilinear motion.

D. Compromise between tangent and curve

* Emphasize that some compromise must be made so that the transition satisfies the mechanics of curvature.

* Explain that the first alternative is to attain a certain portion of the superelevation runoff on the tangent and the remaining portion on the curve.

* State that a proportion has been devised which places 80 percent of the superelevation runoff on the tangent and 20 percent on the curve. Indicate that some design offices use a 70-30 percent proportion.

* Point out that the second alternative is the use of the spiral curve because it provides a natural distance for superelevation runoff.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

E. Length of superelevation runoff

* Emphasize that the length of superelevation is controlled by the difference between the longitudinal slope of the outside edge and the longitudinal slope of the centerline profile.

* Draw figure 15 on the chalkboard and explain the difference in longitudinal slope between edge and centerline profiles.

LONGITUDINAL VIEW OF CENTERLINE AND EDGES OF PAVEMENT

FIGURE 15

* Discuss the allowable differences in longitudinal slopes and emphasize that the design speed is the controlling factor.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

Design Speed in m.p.h.	Maximum relative slope between profiles of edge of two-lane pavement and centerline
30	0.66% or 1/150
40	0.58% or 1/175
50	0.50% or 1/200
60	0.45% or 1/225
65	0.41% or 1/245
70	0.40% or 1/250
75	0.38% or 1/265
80	0.36% or 1/280

* Point out that the criteria above brings the longitudinal slope of the outside edge to within 0.5 percent of the longitudinal slope of the centerline profile if a 50-m.p.h. design speed is used as an example.

F. Superelevation tables

* Use the charts on pages 168-171 of Ref. B to find the proper rate for a given design speed on a given design curve.

* Note that normal crown (N.C.) indicates no change from normal and that remove crown (R.C.) indicates the removal of adverse crown.

* Point out that the required superelevation rate for a 4°-curve at a 50-m.p.h. design speed is 0.063 ft. per foot when e max. is 0.08. (Ref. B, p. 169)

G. Application

* Find the required superelevation rate and the placement of the runoff for a rural, two-lane highway with 10-ft. pavements designed at 50 m.p.h. on a 4°-curve with normal crown section (N.C.S.) of $\frac{1}{6}$ in. per foot (0.021 ft. per foot).

* Sketch figure 16 (on the following page) on the chalkboard and explain how full bank is achieved.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Positions of pavement	* Describe figure 8 as a series of views depicting the cross section of a two-lane pavement as it changes positions from a normal crown section to full bank. * Indicate that the first position is a normal crown section which is assumed to be a $\frac{1}{4}$ in. per foot slope. * Note that in the next position the crown of the right lane remains unchanged while the left lane becomes level. * Emphasize that the next obvious change occurs in the plane slope where the entire pavement (both lanes) is on the original $\frac{1}{4}$ in. per foot slope. * State that the next position is an intermediate view of the pavement between a plane slope and full bank. * Indicate that the last position is the full bank for a particular design speed and given curvature.
2. Composite view	* Draw figure 9 on the chalkboard and state that it is a composite of all the positions and that the numbers at the edge of each lane denote the positions shown in figure 8. (Fig. 9 shown on page 69.)
3. Reasons for centerline pivot	* Explain that the method of pivoting about the centerline profile is the most widely used in design because the required change in the elevation of the pavement edge is made with the least distortion and it is more easily built. * Point out that since the centerline profile remains unchanged, any change in pavement cross slope is divided equally between the two edges when entering full bank. * Mention that when the centerline pivot is used on a four-lane divided

TRAINING COURSE FOR

STENOGRAPHERS

The material in this guide is presented in the form of suggestions. Every student participating in this program will be different in regard to education, experience, and ability. The instructor must, therefore, adjust and adapt the suggestions in this guide to the needs of individual students.

The first step in insuring this adjustment is to secure as much information as possible about each new student. This can be accomplished through study of the pre-enrollment information gathered by the Center counselors. The second step is to keep up to date on the progress of each student through the regular use of the information prepared by Individual Program Control (IPC). With this information on hand the instructor can effectively adapt specific objectives, teaching methods, and time alloted to each aspect of the training, directly to the student's needs.

This guide will aid the instructor in accomplishing part of his job. It will provide performance objectives, suggest time allotments, unit outlines, and supplemental teaching aids. Only the instructor, however, can combine these factors with a knowledge of each individual student.

Course Objectives:

The stenographer program at Gila River Career Center is designed to:

1. develop in the student an awareness of the importance of office work and of the career opportunities which it offers.

2. develop an understanding of the place and purpose of the office in general, and the stenographer in particular, in the typical business organization.

3. develop a job-centered approach to businesslike work habits and attitudes and effective human relations.

4. develop an awareness of the need for continuous concentration on the fundamental skills--grammar, spelling, punctuation, vocabulary building, pronunciation, handwriting, and arithmetic.

5. prepare the student to perform the technical tasks commonly expected of the stenographer.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

highway the entire highway (four lanes) is superelevated as a single section as it rotates about the centerline of the median.

ATTAINMENT OF SUPERELEVATION BY REVOLVING ABOUT CENTERLINE

COMPOSITE VIEW

FIGURE 9

22579

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Revolving pavement about inside edge	* Draw figure 10 on the chalkboard and explain how the pavement is revolved about the inside edge. * Note that in the four-lane divided highway the median is held on a horizontal plane while the two pavements are rotated about the inside or median edge.

ATTAINMENT OF SUPERELEVATION BY REVOLVING ABOUT INSIDE EDGE
SEPARATE VIEWS
FIGURE 10

CONTENT OUTLINE

1. Transposition of theoretical grade-line

TEACHING POINTS AND TECHNIQUES

* Draw figure 11 on the chalkboard and indicate that it is a series of views depicting the cross section of a four-lane pavement as it changes from a normal cross section to full bank.

* Emphasize that the most important element in this type of revolution is the exchange of the theoretical grade-line from the normal position to a plane through the inside edge of the pavement.

ATTAINMENT OF SUPERELEVATION BY REVOLVING ABOUT INSIDE EDGE
COMPOSITE VIEW
FIGURE 11

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Draw figure 13 on the chalkboard and note how an inside edge pivot remedies the problem in figure 12.

4 LANE DIVIDED HIGHWAY
PIVOT AT INSIDE EDGES
FIGURE 13

C. Revolving pavement about outside edge

* Draw on the chalkboard figure 14, found on page 75, and explain how the pavement is revolved about the outside edge.

1. Positions of pavement

* Note that the various positions of the pavement are opposite from the inside edge pivot.

2. Advantages

* Mention that pivoting about the outside edge is the best way aesthetically to superelevate a highway. Also this method keeps at a constant elevation the pavement edge (outside) most noticable to the driver which gives him a feeling of security.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* State that this type of revolution does not affect any part of the design or construction. As a highway is superelevated about the inside pavement edge the elevation of the new gradeline drops below the normal theoretical gradeline (lane width of 12 ft. times ¼ in. per foot = 3 in.).
	* Note that this new gradeline proceeds parallel to the normal theoretical gradeline and as soon as the banking operation is complete, the theoretical gradeline again assumes its normal position.
2. Positions of pavement	* Mention that since the inside edge of the pavement is anchored, the second view shows the right lane in normal position while the left lane is now level and similar to the second view in figures 8 and 9.
	* Point out that the third view is similar to the third view of figure 8.
	* Indicate that in the fourth view the entire plane slope revolves about the inside edge which places the center point above the original theoretical gradeline.
	* Add that in the fifth view the entire two-lane pavement is pivoted to full bank.
3. Reasons for pivoting about inside edge	* Repeat that in this method the inside edge profile is a line parallel to the calculated centerline profile.
	* Show that one-half of the required change in cross slope is made by raising the centerline profile with respect to the inside pavement edge and the other half is accomplished by raising the outside pavement edge an equal amount with respect to the centerline profile.
	* Emphasize that rotating about the inside edge creates better drainage

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

conditions and that this method must be used in the design of a four-lane divided highway when the median is narrow.

* Explain the results when a center pivot is used on a four-lane divided highway with a 4-ft. median.

* Draw figure 12 on the chalkboard and point out the difference in elevation between the two edges of the 4-ft. median.

4 LANE DIVIDED HIGHWAY
PIVOT AT EACH ℄ PROFILE
FIGURE 12

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Indicate that the dimensions for the SU design vehicle (single unit truck with a 20-ft. wheelbase) is always used as representative of all design vehicles.
C. Design values	* State that the cost of widening curves far exceeds the gains accomplished but it is important to do on narrow pavements with sharp curves.
1. Minimum standards	* Explain that the additional width on curves should be in multiples of 6 in. starting with a 2-ft. minimum.
2. Widening chart	* Mention that table III-12 on page 186 of Ref. B indicates the required widening for 24, 22, and 20-ft. pavements at curvatures ranging from 1° to 26.5°.
	* Point out that all values under 2 ft. are to be disregarded and that all values for a four-lane or divided highway should be doubled.
3. Application	* Find the amount of widening required for an undivided four-lane pavement (11-ft. lanes) at a design speed of 50 m.p.h. on a 4°-curve.
	* Note that the chart calls for 1.5 ft. of widening for two lanes which means that it should be doubled to 3 ft. for a four-lane undivided highway.
D. Attainment of widening	* Describe a widening as a gradual change beginning on the approaches of a curve, proceeding through the curve, and ending on the tangent after the curve. (Ref. B, p. 187)
	* State that widening should be done only on the inside edge of simple curves but in the case of the spiral curve, a choice may be made between widening on the inside or dividing the widening on the inside and the outside of the curve.

CONTENT OUTLINE

III. Horizontal Sight Distan

TEACHING POINTS AND TECHNIQUES

* Caution that the change from a normal width to the widened section should occur within 100 to 200 ft. since a long transition results in narrow slivers which are difficult to construct.

* Emphasize that the edge of the widening should be a smooth, graceful curve, not a tangent or a series of tangents.

* Point out that one-half to two-thirds of the transition is placed on the tangent and the remainder on the curve but on spiral curves the transition should occur on the spiral.

* State that widening instructions should be placed on the plans for construction.

ce

* Define the horizontal sight distance as the clear line of sight across the inside of a curve. (Ref. A, pp. 161-163; Ref. B, pp. 188-189; Ref. C, section 22, p. 14)

* Mention the objects which will obstruct visibility.

1. Walls
2. Cut slopes
3. Wooded areas, trees
4. Signs
5. Buildings
6. Hedgerows
7. Farm crops
8. Utility poles

* Explain that the middle ordinate is the distance m from the centerline of the inside lane to any obstruction on the line of sight. (Ref. A, p. 166; Ref. B, p. 188)

* Add that this is not the middle ordinate distance of the design curve.

CONTENT OUTLINE

A. Equations

TEACHING POINTS AND TECHNIQUES

* Note that since only the factors of curvature and sight distance are involved, the equation for m (middle ordinate) is relatively simple.

* Indicate that the formula used by the AASHO to find the middle ordinate is:

$$m = \frac{5730}{D} \text{ vers } \frac{SD}{200}$$

where 5730 is the radius in feet of a 1°-curve

D is the degree of curvature

S is the stopping sight distance along the centerline of the inside lane

vers $\frac{SD}{200}$ equals 1 - cosine $\frac{SD}{200}$

1. Derivation of factor

* Explain how the factor 200 is determined.

* State that the geometry of a simple curve (from surveying) indicates that m (middle ordinate distance measured on a radial line from the curve to the long chord) is found as follows:

$$\cos \frac{\Delta}{2} = \frac{R - m}{R}$$

where Δ is the deflection angle between the tangents

R is the radius of the curve in feet or $\frac{5730}{D}$

m is the middle ordinate distance.

Therefore $m = R\left(1 - \cos \frac{\Delta}{2}\right)$ or

$= R \text{ vers } \frac{\Delta}{2}$

* Note that the geometry of the simple curve also indicates that the length of curve (L) is equal to $\frac{100\Delta}{D}$ and since L is approximately the line of sight distance then:

$$S = 100 \frac{\Delta}{D} \quad \text{or}$$

CONTENT OUTLINE TEACHING POINTS AND TECHNIQUES

ACHIEVEMENT OF FULL BANK

FIGURE 16

* Note that the superelevation rate in this problem is 0.063 ft. per foot. This means that in full bank the outside edge will be 0.063 ft. per foot times the pavement width of 10 ft. or 0.63 ft. above the centerline profile or 0.084 ft. above the outside edge of the normal crown section (0.63 ft. plus 0.21 ft.).

* Draw figure 17 on the chalkboard and explain the change in elevations of the pavement edges.

ELEVATION CHANGES IN PAVEMENT EDGES

FIGURE 17

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Criteria	* Indicate that the longitudinal slope of the outside edge cannot exceed the longitudinal slope of the centerline profile by more than 1/200, or 0.5 percent. This affects the distance that the outside edge can rise from its position in the normal crown slope to its position in full bank. * Note that this rise amounts to 0.84 ft. Show that 0.84 ft. times 200 is equal to 168 ft. and that 168 ft. is the distance in which this transition or superelevation runoff will occur.
2. Apportionment	* Recall the designation of 80 percent on the tangent and 20 percent on the curve and that 80 percent of 168 ft. is 134 ft., which automatically places the beginning of runoff at a point 134 ft. before the P.C. * Add that this also places 34 ft. of the runoff on the curve.
3. Deviation	* Point out that the transition from normal crown section to full bank is on a straight line deviation so that any position may be calculated by direct proportion.
4. Computation of position	* Refer to figure 17 and state that position #2 (remove crown) or #3 (plane slope) is located by a direct proportion with the elevation change in that position. Thus position #2 (left lane) is a level surface with an edge that is 0.21 ft. higher than its edge in the normal cross slope position. The pavement would, therefore, achieve this position at a distance of $\frac{0.21}{0.84}$ times the total distance of 168 ft. or 42 ft. from the point of the beginning of superelevation.
5. Rollover effect	* Describe the rollover effect and explain how the cross section of the

Course Outline:

The following table provides a listing of course units along with time estimates for each unit. Both sequence and estimates can be varied to meet student needs. Units are presented concurrently as students achieve objectives that prepare them to move ahead.

Course Unit	Title	Hours	Code
Unit I	Occupational Orientation	5- 7	-01
Unit II	Fundamentals of Typing	70- 85	-02
Unit III	Production Typing	60- 80	-07
Unit IV	Shorthand Principles	90-100	-11
Unit V	Machine Transcription	15- 20	-12
Unit VI	Office Equipment	20- 30	-03
Unit VII	Communications	15- 20	-04
Unit VIII	Transportation	2- 4	-10
Unit IX	Financial Activities	8- 10	-08
Unit X	Record Management	15- 20	-09
Unit XI	Sources of Information	3- 5	-05

2226

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	shoulders is altered on both the low and high side of a banked section. (Ref. B, p. 251)
IV. Use of Superelevation Runoff	* Summarize this transition of superelevation on a simple curve and emphasize that there can be many solutions to the problem. (Ref. E, p. 11) * Add that many design offices use different apportionments of the runoff to fit certain field conditions but that in general most designs restrict 65 percent to 85 percent of the superelevation runoff to the tangent.
A. Spiral curve	* Draw figure 18 on the chalkboard and review the rudiments of a spiral curve. Note that the principal advantage of a spiral curve is that it provides a natural path for the vehicle. (Ref. B, pp. 172-174; Ref. C, section 22, pp. 13-14; Ref. E, pp. 12-14)

SPIRAL CURVE

FIGURE 18

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Length of spiral	* Explain that in any spiral curve, the length of spiral, which is the curvilinear transition between the tangent and the circular curve, is that distance dedicated to the superelevation runoff. * Emphasize that at the beginning of a spiral curve, a normal cross section (position #1) would rotate to position #2 (removal of crown) but point out that this would leave the left half of the pavement in a negative banked position while on the spiral. * Mention that this unorthodox position forces the driver to steer into the centerline in order to control his vehicle.
2. Tangent runout	* State that to rectify this condition, a tangent runout distance is utilized. This is a distance on the tangent directly before the point of tangency (P.T.) in which the pavement revolves from position #1 to position #2. * Note that this distance is always designated as X.
3. Equation of the tangent	* Indicate that the equation to compute the tangent runout distance X is: $X = \frac{L_s(N.C.S.)}{e}$ where L_s is the length of spiral as indicated on the e max. charts. (Ref. B, pp. 168-171) * Use the chart on page 169 of Ref. B to determine the length of spiral necessary for a given design speed at a given curvature using 0.08 as a maximum. * Add that these charts recommend the use of spiral curves only for cases below the heavy line.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
a. Application	* Find the necessary superelevation, where it begins and where it achieves full bank, for a rural, two-lane highway with 12-ft. lanes, for a 60-m.p.h. design speed on a 3°-curve. * Find the same information when a 180-ft. spiral curve is used.
1. e max.	* Point out that the maximum e for this problem is 0.067 in accordance with the 0.08 e max. chart and note that the longitudinal slope control at 60 m.p.h. is 1/225 or 0.45 percent.
2. Maximum change in elevation	* Indicate that the maximum change in cross slope is 0.021 ft. per foot plus 0.067 ft. per foot or 0.088 ft. per foot. * Add that this maximum change can be computed in actual difference of elevation: 0.021(12) + 0.067(12) = 1.056 ft. * Note that this change in elevation of 1.056 must occur in 238 ft. (1.056 ft. x 225). * Use 80 percent of this transitory distance on the tangent (238 x 0.8 = 190 ft.) and 20 percent on the curve (238 x 0.2 = 48 ft.).
3. Removal of adverse crown	* Indicate that the removal of the adverse crown occurs at a point measured by a direct proportion: $R.C. = \frac{0.021}{0.088} \times 238$ ft. = 57 ft. from the beginning of superelevation * State that the removal of the adverse crown occurs at a point 133 ft. (190-57 = 133) before the P.C.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
4. Pavement in plane slope	* State that the point where the entire pavement is a plane slope is: $\frac{0.042}{0.088} \times 237 = 114$ ft. * Point out that the plane slope position of the full pavement occurs 76 ft. before the P.C. (190 - 114 = 76)
5. Use of the spiral curve	* Compute the tangent runout X when a 180-ft. spiral curve is used. * Explain that there is now 180 ft. of spiral curve to handle the superelevation runoff. $X = \frac{L_s(N.C.S.)}{e}$ $= \frac{180(0.021)}{0.067}$ = 56 ft. * Indicate that the normal cross slope begins to change 56 ft. before the point of tangent to spiral (P.T.S.) and is completely removed at the P.T.S. * Note that the change from the removal of adverse crown to a full bank position will occur in the length of spiral or in 180 ft. * Emphasize that the full bank position occurs at that point where the spiral ends and the circular curve begins (the P.S.C.).

QUESTIONS FOR REVIEW

1. What is the e max. for a rural highway in New York State?
2. What is superelevation runoff?
3. Name three methods of attaining superelevation.
4. List the four steps in which a pavement reaches a superelevated position.

5. What is the superelevation of the right-hand lane on a tangent section of a two-lane highway?

6. What is the most widely used method of rotating a pavement for superelevation?

7. How does the transposition of the theoretical gradeline to an inside edge of pavement affect the profile of a highway?

8. Explain the problems which may result if a four-lane divided highway with a 20-ft. median were pivoted about the centerline of each pavement section.

9. Why would a four-lane divided highway be pivoted about the outside edges?

10. Describe the solution to the problem of superelevation in the vicinity of a tangent approaching a curve.

11. What is the maximum deviation between the longitudinal slope of the centerline profile and the pavement edge profile of a highway designed for 50 m.p.h.?

12. What is the relationship between a spiral curve and its tangent which makes it compatible for superelevation runoff?

13. Why is a tangent runout necessary on a spiral curve?

14. What is e for a 6°-curve at 70 m.p.h. when e max. is 0.08?

15. What is the e max. for an arterial highway in New York State?

ASSIGNMENTS

1. Study pages 151, 161-182 in Ref. A, and pages 183-192; 310-323; 332-358; 366-377 and 387-391 in Ref. B.

2. Find the placement of superelevation runoff with respect to the P.C. for a 5°-curve on a rural, two-lane highway with 10-ft. lanes and a design speed of 60 m.p.h.

3. Find the tangent runout if a spiral curve is used in #2.

Lesson 8 - Elem

OBJECTIVES

- To provide some of the
- To develop an understan horizontal alinement

CONTENT OUTLINE

I. General Horizontal Contr

†Reference citations are shown

ents of Horizontal Alinement

fundamental elements of horizontal alinement
ding of some of the general controls used in

TEACHING POINTS AND TECHNIQUES

ols * Indicate that a number of general horizontal controls are used to insure a safe, smooth flowing highway. (Ref. B, pp. 190-192)†

1. Make alinement as directional as possible but consistent with topography.

2. Avoid use of the maximum allowable curvature.

3. Hold alinement consistent and avoid any sudden changes.

4. Avoid short curves for small deflection angles. Use a minimum of 500 ft. (length of curve) for a central angle of 5°-curve with the minimum length increasing 100 ft. for each 1° decrease in central angle.

5. Avoid sharp curvature on high, long fills.

6. Avoid compound curves, but whenever one must be used, the radius of the flatter curve (R_L) should be no more than 50 percent greater than the radius of the sharper curve (R_S).

7. Avoid reverse curves and note that a reversal in alinement

on page 220.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

makes it difficult for a driver to remain in his own lane since proper superelevation is impossible.

8. Avoid broken-back curves by using a long, simple curve or by compounding the curvature.

9. Balance all horizontal alinement with vertical design.

II. Pavement Widening

* State that operating conditions on curves should be comparable to those on tangents. (Ref. A, p. 151; Ref. B, p. 183)

* Point out that on certain highways this is accomplished by widening the pavement on the curves so there is no difficulty in steering.

* Note that widening was the accepted practice when most pavements were narrow but with the advent of the 12-ft. lane, the need for widening has been restricted to the narrow highway of low classification.

A. Reasons for widening

* Emphasize that when a vehicle traverses a curve without superelevation, the rear axle is radial and the rear wheels track inside the front wheels.

* Point out that a vehicle traveling at excessive speed on a superelevated curve may also have the rear wheels outside the front wheels. This situation also creates a problem in steering if the pavement is too narrow.

* Note that this additional width of occupied pavement can be computed by geometry but when the pavement is superelevated it becomes difficult to determine the amount of this off-tracking.

B. Derivation of required widening

* Explain the equation used for the widening of pavements on curves. (Ref. B, p. 184)

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

Design Speed	Maximum Curvature
30 m.p.h.	21°
40 m.p.h.	14°
50 m.p.h.	10°
60 m.p.h.	6°
70 m.p.h.	3°

IV. Intersections

* Define an intersection as the area where two or more highways join or cross. (Ref. A, pp. 166-168; Ref. B, p. 308, pp. 387-391; Ref. C, section 22, p. 27)

* State that there are three types of intersections.

1. Intersections at grade
2. Grade separations without ramps
3. Interchanges

A. Design factors

* Mention that there are many possible designs for intersections and interchanges, all with advantages and limitations.

* Add that the coordination of traffic in certain topographical conditions poses a difficult problem for the designer.

* Emphasize that the primary factors in the choice of an intersection design are:

1. Volume of traffic
2. Composition of traffic
3. Highway design speed
4. Service to traffic
5. Physical condition of the area
6. Cost of right-of-way.

B. Intersections at grade

* Indicate that the geometric forms used for intersections include (Ref. A, p. 168; Ref. B, p. 388):

1. three-leg (T or Y)
2. four-leg
3. multileg
4. rotary

22604

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Style of intersection	* Point out that any of these forms can be flared or channelized, or both.
a. Flared intersection	* Define a flared intersection as one where additional traffic lanes have been added.
	* State that the elimination of parking in the intersection area serves the same purpose as flaring.
b. Channelized intersection	* Show the difference between a channelized intersection and a flared intersection by noting the various channelizing devices used such as lane markings, separators, medians, and islands.
2. Forms of intersection	* Note that there can be an infinite number of intersection shapes and patterns but only the simple forms will be discussed.
a. Three-leg intersection	* Mention that the junction of three highways is called a branch, T, or Y intersection. (Ref. B, pp. 438-460)
(1) Branch	* Indicate that the branch is an offshoot of a major highway, usually at a small deflection angle.
(2) T	* Explain that the T is an intersection of two highways with one at, or nearly at, a right angle to the other.
(3) Y	* State that the Y intersection is one in which three highways meet at nearly equal angles.
b. Four-leg intersection	* Add that the four-leg intersection is the most common and consists of two highways crossing either at right angles or at some angle with each other. (Ref. B, pp. 461-475)
c. Multileg intersection	* Emphasize that the addition of another highway to the normal four-leg intersection creates a multileg intersection which presents many problems of traffic control. (Ref. B, pp. 476-477)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
d. Rotary intersection	* Point out the rotary intersection, or traffic circle is one in which all the traffic flows one way around a central island. (Ref. A, p. 171; Ref. B, pp. 478-491) * Mention that rotary intersections are often used to replace existing multileg intersections.
(1) Advantages	* State the advantages of the rotary intersection. 1. Traffic proceeds in an orderly manner with little delay. 2. Direct confrontation of traffic is eliminated. 3. Turning is easy. 4. The rotary is well suited for intersections with five or more legs. 5. The cost of construction is low compared with an interchange.
(2) Disadvantages	* Point out the disadvantages of the rotary. 1. Congestion begins on the rotary when two or more approach highways reach capacity at the same time. 2. A large amount of right-of-way is required. 3. The surrounding topography must be reasonably flat. 4. The rotary is not suitable for pedestrian movement. 5. Rotaries for high speed highways need to be large and this means extra driving for most vehicles.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	6. Many signs and ample lighting are required.
e. Traffic islands	* Define a traffic island as a triangular or elongated area between traffic lanes. (Ref. A, pp. 168-171; Ref. B, pp. 368-377)
(1) Purposes	* List the following purposes of the traffic island in intersection design: 1. Separation of conflicting traffic 2. Control of angle of conflict 3. Reduction in excessive pavement areas 4. Regulation of traffic 5. Channelization of certain movements 6. Protection for pedestrians 7. Protection and storage for crossing and turning vehicles 8. Location for traffic control devices 9. Area for loading and unloading public transit riders
(2) Types	* Indicate that all traffic islands are divided into three functional groups.
(a) Directional	* State that the directional island is designed to control and direct traffic movement in such a way that crossing streams of traffic cross at right angles and merging streams of traffic converge at flat angles.
(b) Divisional	* Explain that the divisional island divides opposing or same direction streams of traffic. It is useful in the control of turning traffic at skewed intersections.
(c) Refuge	* Describe the refuge island as a safety zone for pedestrians. A high barrier curb is considered essential for this type of island.

22607

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
d. T or trumpet interchange	* State that the trumpet interchange is known as a three-leg interchange and is especially adaptable to T intersections. * Compare this interchange with the others and note that it is directional since all turns are made in the direction of destination.
e. Y interchange	* Note that the Y interchange is comparable to the T and that it is also directional.
f. Directional interchange	* Indicate that the directional interchange has ramps for one or more left turning movements on directional alinement. * State that this interchange requires more than one bridge or one bridge with more than two levels.
g. Rotary interchange	* Point out that the rotary interchange is comparable to the rotary intersection at grade except that the major highway is separated from all other roadways. * Mention that other approach highways and diamond-patterned ramps are connected by the rotary. * Add that this interchange is excellent for a multileg intersection.
h. Advantages of the interchange	* Indicate the advantages of the interchange. 1. Traffic capacity is about the same within the interchange as it is outside the interchange. 2. There is an increase in safety for through traffic and left-turning traffic. 3. It is flexible in design and may be adapted to any topographical condition.

22609

UNIT I (14.0703-01)

OCCUPATIONAL ORIENTATION

Performance Objectives:

Upon completion of this unit the student will be able to describe orally the general purpose and organization of business. She will be able, as determined by instructor observation, to demonstrate good interpersonal relations with other class members and good organization of a work station.

The student will be able to demonstrate in a role playing, or other simulated situation, the proper dress and grooming for an office worker and correct techniques and good manners. She will be able to score 80% on an objective test covering the responsibilities of a stenographer.

Unit Outline:

A. Review of Modern Business Enterprise

1. Methods of organization

2. Purposes of business

B. Types of Offices and Opportunities for Office Workers

C. What Business Expects of Office Workers

1. General expectations

2. Appropriate attire

3. Posture and figure control

4. Complection and health

5. Personal hygiene

D. Office Techniques of Etiquette

1. Basic good manners

2. Application of social graces to office situations

3. Some special problems that occur

E. Interpersonal Relations

1. Role of motive and emotion

2. The office worker's role in business-human relations activities

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	4. It may be easily adapted to stage construction.
i. Disadvantages of the interchange	* Give the disadvantages of the interchange.
	1. Engineering, right-of-way, construction, and maintenance are costly.
	2. The unconditioned driver can become confused.
	3. Long approaches necessary in flat country are costly and reduce sight distance.
	4. The ordinary interchange cannot handle a multilege intersection.
V. Turns	* Point out that the principal control for the design of turning roadways is the alinement of the inner edge of pavement and the width of the roadway channel. (Ref. B, pp. 319-323)
	* Mention that this is necessary to provide accommodation for the design vehicle at low speed.
A. Design of turns	* Discuss minimum design for turns at an intersection. Explain plotting the paths of a design vehicle on each turn and fitting curves or combinations of curves to the paths of the inner rear wheels of the design vehicle.
	* Refer to table VII-1 in Ref. B, page 318, which is used in the design of any angled intersection and for all design vehicles.
1. Selection of vehicle design	* Indicate that after studying all the traffic information the choice of a design vehicle for criteria in designing an intersection is simply one of judgment.
	* Point out that it would be foolish to select a WB-50 as the design vehicle

22610

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

$$\Delta = \frac{SD}{100}$$

* Multiply both terms by $\frac{1}{2}$ to get the deflection angle in terms of $\frac{\Delta}{2}$ and the expression becomes:

$$\frac{\Delta}{2} = \frac{SD}{200} \quad \text{also}$$

$$m = R \text{ vers } \frac{\Delta}{2}$$

Substituting $\frac{SD}{200}$ for $\frac{\Delta}{2}$ then

$$m = R \text{ vers } \frac{SD}{200} \quad \text{and}$$

$$R = \frac{5730}{D} \quad \text{then}$$

$$m = \frac{5730}{D} \quad \text{vers} \quad \frac{SD}{200}$$

* Emphasize that this formula does not apply when the length of the circular curve is less than the sight distance or when the radius of the curve is not constant.

* Add that since it is difficult to separate S from the equation (and often S may be desired when m is known) the following equation is used:

$$S = \frac{200}{D} \cos^{-1}\left(\frac{R - m}{R}\right)$$

B. Application

* Mention that in most instances a rough horizontal sight distance can be determined graphically from the plans but that if an accurate m distance is required, the equation must be used. (Ref. B, p. 150, figure III-3)

* Point out that the m distance may be measured graphically and the available stopping sight distance computed.

320

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Emphasize that the stopping sight distance is directly related to the design speed.

* Find the distance from the centerline of the inside lane to an obstruction on a 5°-curve with a design speed of 60 m.p.h.

* Relate that a 5°-curve has a radius of 1146 ft. and that a design speed of 60 m.p.h. requires a stopping sight distance of 475 ft.

* Use the following equation:

$$m = R\left(1 - \cos \frac{SD}{200}\right)$$

$$= 1146\left(1 - \cos \frac{475(5)}{200}\right)$$

$$= 1146\ (1 - \cos 11.875°)$$

$$= 1146\ (1 - \cos 11° 53')$$

$$= 1146\ (1 - 0.97857)$$

$$= 1146\ (0.02143)$$

$$= 24.6 \text{ ft.}$$

* State that m of 24.6 ft., measured on a radial line, is the allowable distance from the centerline of the inside lane to any obstruction in order to preserve the sight distance of 475 ft.

* Mention that the radius of 1146 ft. is measured along the centerline of the highway but note that if it were decreased by the half-lane distance, the difference in m would be negligible.

* Determine if an m distance of 100 ft. is satisfactory for a 3°-curve with a design speed of 70 m.p.h.

22602

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

$$S = \frac{200}{D} \cos^{-1}\left(\frac{R-m}{R}\right)$$

$$= \frac{200}{3} \cos^{-1}\left(\frac{1910 - 100}{1910}\right)$$

$$= 66.7 \cos^{-1} (0.94764)$$

$$= 66.7 (18.6)$$

$$= 1240 \text{ ft.}$$

* Indicate that the stopping sight distance for a 70 m.p.h.-design speed is 600 ft.

* Solve the preceding problem when the m distance is 23 ft.

$$S = \frac{200}{3} \cos^{-1}\left(\frac{1910 - 23}{1910}\right)$$

$$= 66.7 \cos^{-1} (0.98796)$$

$$= 66.7 (8.9)$$

$$= 593 \text{ ft.}$$

* State that the 593 ft. of sight distance is not sufficient for a 70-m.p.h. design speed.

* Describe a situation with a cut slope on the inside of a curve and discuss with the class the computation of a minimum m distance which varies with the back slopes. (Ref. B, p. 189)

* Mention that one of the worst driving conditions occurs at night because the limited lateral spread of a headlight beam keeps the inside edge of the pavement from being visible for the required stopping sight distance. (Ref. B, section 22, p. 15)

* List the maximum curvatures for each design speed when using this criteria, noting that this is a 1960 specification.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
C. Grade separations	* State that a grade separation at an intersection of two highways permits the crossflow of traffic to proceed at different levels without interruption. (Ref. A, pp. 172-178; Ref. B, pp. 492-500)
1. Reasons for use	* Point out that the grade separation is used to facilitate the rapid movement of vehicles on high density traffic highways. Also that certain topographical features may demand this treatment.
2. Without ramps	* Mention that grade separation without ramps is used when a major highway crosses another major highway, a minor highway, or a railroad.
3. With ramps - interchanges	* State that there are seven types of interchanges. (Ref. A, p. 174; Ref. B, p. 494)
a. Cloverleaf	* Note that the cloverleaf has a full complement of ramps with a separate one-way ramp for each turning movement. (Ref. A, Fig. 5-26, p. 176) * Indicate that it is not possible to make a left-hand turn. Note that a driver who wants to turn left must pass road intersection and turn right for 270°
b. Partial cloverleaf	* Explain that the partial cloverleaf is a two-quadrant interchange without a full complement of ramps and where all movements are provided for but does allow left turns into the minor road.
c. Diamond interchange	* Mention that the diamond interchange is excellent for a limited right-of-way but does permit left or right turns into the minor highway. * Add that this is usually the least costly of all interchanges. It is also flexible since it can serve higher densities of traffic by merely increasing the number of lanes on the ramps and on the major highway.

22608

MICROCOPY RESOLUTIO
NATIONAL BUREAU OF ST

N TEST CHART
ANDARDS-1963-A

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Critical length of grade	* Emphasize that maximum grade in itself is not a complete design control since the length of grade can often slow up truck traffic enough to critically affect highway capacity. (Ref. B, pp. 195-203)
	* State that critical length of grade is the maximum length of an upgrade a loaded truck can operate on without an unreasonable reduction in speed.
	* Indicate that charts can be made which designate the critical length of grade for any condition of grade, approach grade , and speed.
	* Note that the general design guide has been established at a 15 m.p.h. reduction in speed for a grade.
a. Graph for design	* Explain how to use the graph, Critical Lengths of Grade for Design, in Ref. B, figure III-17, page 200.
	* Show that the critical length of grade is 1100 ft. for a 4-percent grade with a level approach at a design speed of 60 m.p.h.
	* Add that if the design speed is 40 m.p.h., the initial and minimum tolerable speeds on the grade are different, but for the same permissible speed reduction, the critical length of grade is still 1100 ft.
b. Vertical rise criteria	* Indicate that another design guide for the critical length of grade is the amount of vertical rise resulting from the 15 m.p.h. reduction in speed.
	* State that this total rise is 35 ft. for an 8-percent grade, 44 ft. for a 4-percent grade, and 55 ft. for a 2.5-percent grade.
c. Excess of critical grade	* Point out that when the critical length of grade is exceeded, an added uphill lane for slow moving vehicles must be considered.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
III. Vertical Curves	* Review the elements of the vertical curve as outlined in the unit on surveying.
A. Types	* Refer to the sketches in figure III-18 in Ref. B, page 202 and show that all vertical curves are divided into four types.
	* Note that type I covers the crest vertical curve which consists of an ascending grade followed by a descending grade.
	* Explain that type II is also a crest vertical curve but it can be an ascending grade followed by a flatter ascending grade or a descending grade followed by a sharper descending grade.
	* Mention that type III is a sag vertical curve consisting of a descending grade followed by an ascending curve and the opposite of type I.
	* Indicate that type IV is a sag vertical curve and is either a descending grade followed by a flatter descending grade or an ascending grade followed by a sharper ascending grade and the opposite of type II.
B. Design control	* State that considerations in the design of vertical curves are safety, comfort, appearance, simplicity in application, and adequacy of drainage. (Ref. A, pp. 152-153; Ref. B, pp. 203-209)
1. Safety	* Emphasize that the safety design factor on crest vertical curves is the minimum stopping sight distance.
2. Comfort	* Point out that comfort is important, especially in the sag vertical curve where gravitational and vertical centrifugal forces act in the same direction.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Appearance	* Note that appearance is important for psychological reasons.
	* State that long curves give a pleasing appearance but short curves give the profile a broken look.
4. Simplicity	* Reiterate that the vertical curve can be circular, parabolic, or cubic parabolic but that for ease in computing, designing, and constructing, the parabolic curve is used.
5. Drainage	* Mention that the drainage of curbed pavements on sag vertical curves is a difficult problem.
	* Add that the pavement cross slope can be increased and a drop inlet placed at the low point.
	* Indicate that three drop inlets should be placed in the gutter line, one at the low point and one on each side of this point but 0.2 ft. higher.
IV. Properties of the Vertical Curve	* Point out that highway length measurements are made on the horizontal plane rather than on the profile slope.
	* Note that since most highway grades are relatively flat, there is no practical error in using the parabola for a vertical curve.
A. Calculations	* State that the vertical offsets from the tangent vary with the square of the horizontal distance from the curve end (point of tangency).
	* Add that elevations along the curve are calculated simply as proportions of the vertical offset at the point of vertical intersection (P.V.I.).
B. Rate of change	* Describe the rate of change of grade to successive points on the curve as a constant amount for equal increments of horizontal distance.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	width for the three cases and also utilizes four types of design vehicles: P, SU, WB-40, and WB-50.
3. Pavement width by composition of traffic	* Add that table VII-7 in Ref. B, page 338 furnishes more detailed information about pavement widths for each of the three cases. Also it alters the pavement width in recognition of the composition of traffic.
	* Explain that three conditions of traffic are described (A, B, and C) and that although the predominant vehicle is the control, some consideration is given to other traffic.
a. Traffic condition A	* State that traffic condition A is predominantly P vehicles with some SU vehicles and this forces an increase in the minimum width given in table VII-6 in Ref. B, page 337.
b. Traffic condition B	* Note that in traffic condition B the SU vehicles govern the design but that also some consideration is given to semi-trailers.
c. Traffic condition C	* Point out that in traffic condition C semi-trailers (WB-40 and WB-50) govern the design.
4. Modifications due to pavement edge	* Emphasize the importance of the type of pavement edge and show with table VII-7 in Ref. B, page 338 that a barrier curb will require more width than a mountable curb.
VI. Speed-Change Lanes	* Indicate that a speed-change lane is an auxiliary lane, including tapered areas, primarily for the acceleration or deceleration of vehicles entering or leaving through traffic lanes. (Ref. B, pp. 341-358)
A. Purpose	* State that the primary purpose of the speed-change lane is to provide a physical assistance to the driver so that he can maneuver his vehicle into the necessary change between the speed of the highway and the speed of the ramp.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Uses	* Discuss the advantages and uses of speed-change lanes.
	* Mention the problems which occur on highways without extra lanes at intersections or at ramps.
C. Deceleration lanes	* Discuss the sketches shown in figure VII-13 in Ref. B, page 343 and note that there are three basic types of deceleration lanes.
1. Full lane width	* State that the full width deceleration lane gives the approaching driver a target so that he knows he may maneuver and decelerate on the full lane ahead.
	* Note that some pavement may be saved by beginning with a 6-ft. lane.
2. Tapered lane	* Point out that the tapered lane consists of an outside edge which angles from 4° to 5° with the inside edge.
	* Add that it becomes full width in approximately 140 ft. and show how this saves pavement.
	* Explain that contrasting pavements should be used to make tapering effective.
3. Direct path	* Indicate that the direct path method of designing a deceleration lane is preferred for major turning movements since the deceleration lane may be extended beyond the approach nose.
	* Note that the approach nose is that point where the added lane leaves the traveled way.
	* Mention that this design takes more space but that the distance from the approach nose may be proportioned to the speed differential between the highway and the ramp.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
D. Acceleration lanes	* Refer to the sketch in figure VII-13, Ref. B, page 343 and point out that there are two types of acceleration lanes.
1. Direct path	* State that the direct path acceleration lane is used for low volume highways. * Explain that the direct path acceleration lane consists of a full lane and a taper but note that most drivers never use much of the full lane.
2. Long taper	* Indicate that the long taper acceleration lane is preferred since as much of the speed-change lane as possible should be adjacent to the traveled way. * Mention that there should be no barrier at the far end of this taper.
E. Dimensions	* Emphasize that the dimensions of speed-change lanes are all based on design values and that the length, width, and taper are all computed.
1. Length (deceleration lane)	* Note that the length of the deceleration lane is based on three factors in combination. 1. The speed at which drivers maneuver into the auxiliary lane 2. The speed at which drivers turn after traversing the deceleration lane 3. The manner of decelerating
2. Length (acceleration lane)	* Add that the length of the acceleration lane is also based on three factors in combination. 1. The speed at which drivers merge with through traffic

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	2. The speed at which drivers enter the acceleration lane 3. The manner of accelerating * State that table VII-10 in Ref. B, page 351 furnishes all the required information for the length of all speed-change lanes.
3. Width	* Mention that the width of a speed-change lane may be 11 or 12 ft. but 12 ft. is preferred. * Emphasize that although a full shoulder is not necessary on any speed-change lane, it is still advisable to use a partial shoulder with some stabilization.
4. Taper	* Point out that the length and shape of the taper should encourage drivers to use it. * State that table VII-9 in Ref. B, page 347 shows a listing of tapers used only in conjunction with designed full width speed-change lanes.

QUESTIONS FOR REVIEW

1. What is the minimum length of a horizontal curve when the central angle is 4°?
2. Is it possible to compound a 1°-curve with a 5°-curve and still remain within the bounds of good design?
3. What is the relationship between the rear and front wheels of a vehicle when the vehicle is rounding a curve?
4. When would it be advisable to widen a 24-ft. pavement?
5. How much of the widening transition should be on the tangent?
6. Why is the formula for the m factor in horizontal sight distance determined from the inside lane centerline?
7. Discuss the problem of nighttime sight distance when driving on a curve.

F. Personal Attributes

1. Punctuality

2. Physical health

3. Integrity

4. Leadership

5. Attitudes

G. Personal Efficiency in Identifying Responsibility, Planning and Organizing Work and Work Stations.

Supplemental Teaching Aids:

Excellent resource people for this unit are working secretaries, State Department of Vocational Education personnel, beauty school operators or department store buyers.

The best general resource book is the Arizona State Department of Vocational Education's Suggested Curriculum Guide in Vocational Office Procedures. A good resource for role playing is Case Problems: for Vocational Office Block Project. This is available from the Department of Vocational Education also. Other useful resource books are: You as a Secretary, Royal Typewriter Company. How to be a Super Secretary, Remington Rand, and Sheaffer's Handbook for Secretaries, W. A. Sheaffer Pen Co., Fort Madison, Iowa ($1).

Some very good films are applicable to this unit. For example; "Office Etiquette (15 min.), Britannica Press, Chicago, Ill., "Office Teamwork" (12 min.), Britannica Press, and "Off to a Beautiful Start", Scott Paper Co., Philadelphia, Pa.

Training Time 5-7 hours

8. Define an intersection and name three types of intersections.

9. What is a flared intersection?

10. Describe the three-leg intersection.

11. What are the advantages of a rotary intersection?

12. What are the disadvantages of a rotary intersection?

13. Give five uses of the traffic island.

14. Differentiate between the directional and divisional island.

15. Name seven types of interchanges.

16. Describe the traffic movements in a diamond interchange.

17. What is the greatest advantage of any interchange?

18. How is the width of a turning roadway classified?

19. Discuss how all types of vehicles are able to turn at an intersection designed for automobiles.

20. What is a speed-change lane?

ASSIGNMENT

1. Ask the students to make a simple sketch of three interchanges complete with traffic arrows.

2. Study pages 152-154 in Ref. A; pages 192-214, 438-460, and 476-499 in Ref. B.

INSTRUCTOR'S NOTES

22616

Lesson 9 - Vertical Alinement (Criteria and Controls)

OBJECTIVES

- To present the criteria used to select vertical alinement
- To provide a code for combining controls of horizontal and vertical alinement

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Criteria for Sight Distance	* Indicate that in Lesson 4 the mechanics of sight distance was discussed and point out that in this lesson sight distance as a control of vertical curvature will be analyzed.
A. Measurement of sight distance	* Note that sight distance along a highway is measured from the driver's eyes to an object when it first comes into view on the traveled way. (Ref. B, pp. 147-151)†
1. Height of eyes	* State that in 1965 the AASHO established 45 in. as the height of the driver's eyes above the road surface.
2. Height of object	* Mention that for the minimum stopping sight distance, the AASHO set 6 in. as the height of an object; for passing sight distance, the height was 54 in.
3. Department's criteria	* Add that the State Department of Transportation uses 44 in. as the height of the driver's eyes and 4 in. as the height of an object for the minimum stopping sight of distance.
B. Determination of sight distance	* Ask the students to study the profile of a highway section as shown in Ref. B, figure III-3, page 150. * Point out the stations, the centerline grade, the vertical curve, and the sight distance record below the profile.

†Reference citations are shown on page 220.

22617

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Plastic strip	* Exhibit a transparent plastic strip used to check sight distances graphically.
	* Describe the strip as being 4.5 ft. wide, with scratched lines 4 in. and 44 in. from the upper edge based on a vertical scale of 1 in. = 10 ft.
a. Use	* Place the 44-in. line on the station from which the sight distance is desired and pivot the strip about this point until the upper edge is tangent to the profile.
b. Measurement of stopping sight distance	* Note that the distance between the initial station and the station on the profile intersected by the 4-in. line is the stopping sight distance.
c. Measurement of passing sight distance	* Explain that the distance between the initial station and the station on the profile intersected by the lower edge of the strip is the passing sight distance.
2. Sight distance record	* Correlate the sight distances shown below the profile with the measurements made by the plastic strip.
3. Application	* Demonstrate the actual checking of a profile by using a sheet from a current contract plan.
	* Have each student check the sight distances from different stations and caution that the sight distances should be measured from both directions.
II. Grades	* Emphasize that highway design should give special consideration to proper grades and sight distances.
A. Effect of grades	* Mention that grades affect trucks more than passenger cars.
	* Note that trucks average about 6 m.p.h. less than cars and that truck speeds generally follow an erratic pattern. (Ref. B, pp. 192-194)

22618

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Upgrades	* State that studies indicate, for example, a truck entering a 6-percent grade at 47 m.p.h. will only be going 25 m.p.h. after a 1000 ft.
a. Weight-power ratio	* Point out that the weight-power ratio is 400 pounds per horsepower. * Explain that a ratio must be established so that a designer will recognize a critical grade.
2. Downgrades	* Mention the reason that trucks gain speed on downgrades of 5 percent or less but that they lose speed on downgrades of 7 percent or more.
B. Minimum grades	* Explain that a flat and level grade on uncurbed pavements is no problem if the pavement is adequately crowned. * Emphasize that the curbed pavement should not have less than a 0.5-percent grade except in such cases as a high type concrete pavement on excellent subgrade where 0.35 percent may be used.
C. Maximum grades	* State that the maximum grades now used have been determined by a number of studies made over the years. * Note that at the maximum design speed a 3-percent grade is considered maximum while at the minimum design speed, a 6-percent grade is maximum.
1. Warrant for grade increase	* Show that these maximums may be raised in accordance with general topographical conditions. (Ref. B, table III-13, p. 195) * Add that the maximum grades for the intermediate design speeds are fitted between these extremes. * Mention that for secondary roads or low volume rural roads the maximum grade may be increased by 2 percent. Grades under 500 ft. long or one-way downgrades may be 1 percent steeper.

22619

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	when such a tractor and trailer unit seldom uses the intersection.
2. Selection of turn	* Note that table VII-1 provides the minimum designs for a simple curve and also offers comparable results with a symmetrical and an asymmetrical three-centered compound curve. * Emphasize that much pavement can be saved by using the proper curve. * Discuss the sketches of curves shown in figure VII-1 to VII-4 in Ref. B, pages 310-314.
3. Increase in size of intersection	* State that to prevent the size of the intersection from becoming excessively large, it is wise to provide a corner island or some type of channelization. * Indicate that figure VII-6 in Ref. B, page 321 and table VII-2 in Ref. B, page 322 illustrate the use of a corner island.
B. Widths of turning roadways	* Explain that the widths of turning roadways are classified for three types of operation. (Ref. B, pp. 332-340) 1. One lane - one-way operation and no provision for passing 2. One lane - one-way operation with provision for passing a stalled vehicle 3. Two lane - either one-way or two-way operation
1. Derivation of pavement widths	* Note that figure VII-11 in Ref. B, page 333 illustrates the fundamental differences for the three cases by using a theoretical vehicle.
2. Pavement width for each design vehicle	* Emphasize that table VII-6 in Ref. B, page 337 shows the derived pavement

22611

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Measurement of rate of change	* Mention that this rate of change is measured as the algebraic difference between intersecting tangent grades divided by the length of curve in feet or A/L in percent per foot.
2. Reciprocal of rate of change	* Indicate that the reciprocal, L/A, is the horizontal distance in feet which is necessary to effect a 1-percent change in gradient.
3. Measurement of curvature	* Point out that L/A is a measure of curvature termed K. * State that most tables use the factor K in assessing a given vertical curve.
V. Design Criteria	* Emphasize that when the minimum length of a crest vertical curve satisfies the minimum stopping sight distance requirements, it usually fits all other requirements.
A. Basic equations	* Write the two basic equations on the chalkboard and explain that both equations are solved, but only the appropriate one is used. (Ref. B, p. 204) 1. When S > L, $L = 2S - \frac{1398}{A}$ 2. When S < L, $L = \frac{A\,S^2}{1398}$ where L = length of the vertical curve in feet S = minimum stopping sight distance in feet A = algebraic difference in grade in percent
B. Application	* Find the stopping sight distance provided by a 500-ft. crest vertical curve when A is 5 percent. * Note that since L is known, solve for S. 1. First try S > L assuming that S is greater than L.

22623

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	$L = 2S - \frac{1398}{A}$ $2S = \frac{1398}{A} + L$ $= \frac{1398}{5} + 500$ $= 280 + 500$ $= 780$ ft. $S = 390$ ft. * Check the assumption of S > L or 390 > 500, which is not true, so this formula is null and void. 2. Now try S < L $L = \frac{AS^2}{1398}$ $S^2 = \frac{1398\ L}{A}$ $= \frac{1398\ (500)}{5}$ $= \sqrt{139{,}800}$ $= 374$ ft. * Check the assumption of S < L or 374 < 500, which is true, so the actual stopping sight distance for this design is 374 ft. * Find the length of a crest vertical curve when A is 5 percent with a 60-m.p.h. design speed. * Note that the minimum stopping sight distance for a 60-m.p.h. design speed is 475 ft. 1. First try S > L, where L is known and S is unknown.

22624

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

$$L = 2S - \frac{1398}{A}$$

$$= 2(475) - \frac{1398}{5}$$

$$= 950 - 280$$

$$= 670 \text{ ft.}$$

* Check the assumption of S > L or 475 > 670, which is not true, so this formula is void.

2. Now try S < L

$$L = \frac{AS^2}{1398}$$

$$= \frac{5(475)^2}{1398}$$

$$= \frac{5(225,625)}{1398}$$

$$= 807 \text{ ft.}$$

* Check the assumption of S < L or 475 < 807, which is true, so the actual design length of curve is 807 ft. (rounded off to 800 ft.)

1. Graphs

* Refer to figure III-19 on page 205 in Ref. B and check the problem just computed.

2. Use of K factor

* Note that table III-14 on page 206 in Ref. B computes the same problem by utilizing a rounded K factor.

* Point out that for a 60-m.p.h. design speed with a stopping sight distance of 475 ft. the K value is 160.

* Note that

$$K = \frac{L}{A}$$

or

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

$$L = (A)\ (K)$$

$$= (5)\ (160)$$

$$= 800 \text{ ft.}$$

C. Passing sight distance criteria

* State that it is impractical to use the passing sight distance criteria for the minimum length of curve since in this case the length of curve becomes too long.

* Discuss the information shown on page 207 in Ref. B which requires a 6700-ft. length of curve for the problem just completed. This table shows a K value of 1340.

$$L = (A)\ (K)$$

$$= (5)\ (1340)$$

$$= 6700 \text{ ft.}$$

VI. Design Criteria for the Sag Vertical Curve

* Indicate that at the present time there is no simple, widely used design criteria for computing lengths of sag vertical curves. (Ref. B, p. 208)

* Mention that at least four different criteria are recognized.

1. Headlight sight distance
2. Rider comfort
3. Drainage control
4. Rule of thumb for general appearance

A. Headlight sight distance criteria

* Emphasize that headlight sight distance is the control now being used in New York State.

* Explain that since the amount of highway lighted is directly dependent upon the position of the headlight (2.0 ft. above the ground) and upon the angle of divergence (1° upward), the following equations show the relationship of stopping sight distance, the length of curve, and the algebraic difference in grades.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

1. When S > L

$$L = 2S - \frac{400 + 3.5S}{A}$$

2. When S < L

$$L = \frac{AS^2}{400 + 3.5S}$$

* Note that for overall safety on highways, a sag vertical curve should be long enough so that the light beam distance is the same as the minimum stopping sight distance.

1. Application

* Find the length of curve for a sag vertical curve when A is 6 percent and the design speed is 60 m.p.h.

* Indicate that the minimum stopping sight distance for 60 m.p.h. is 475 ft.

1. First try S > L

$$L = 2A - \frac{400 + 3.5S}{A}$$

$$= (2)\ (475) - \frac{400 + 3.5(475)}{6}$$

$$= 950 - \frac{400 + 166.25}{6}$$

$$= 950 - 344$$

$$= 606 \text{ ft.}$$

* Check the assumption that S > L or 475 > 606, which is not true, so this formula is void.

2. Now try S < L

$$L = \frac{AS^2}{400 + 3.5S}$$

$$= \frac{(6)\ (475)^2}{2062.5}$$

$$= \frac{1,353,750}{2062.5}$$

$$= 656 \text{ ft.}$$

22627

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Check the assumption that S < L or 475 < 656, which is true, so the design length of the sag vertical curve is 656 ft.
B. Comfort effect criteria	* Emphasize that on a sag vertical curve the comfort effect of change in a vertical direction is greater than on a crest vertical curve because gravitational and centrifugal forces are combining instead of opposing each other. * Mention that riding is comfortable on a sag vertical curve when the centripetal acceleration does not exceed 1 ft. per second per second.
1. Equation	* State that the following empirical equation is used to rate a sag vertical curve for comfort: $L = \frac{AV^2}{46.5}$ where L is the length of curve A is the algebraic difference in grades V is the design speed in m.p.h.
2. Derivation of factor	* Explain how the factor 46.5 is determined. * Mention that centripetal acceleration is equal to: $\frac{v^2}{R}$ where v is measured in feet per second R is measured in feet * Note that since the control is 1 foot per second per second then: $\frac{v^2}{R} = 1$ * State that the conversion of v (feet per second) to V (miles per hour) may be done by using a factor consist-

22628

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

ing of the square of feet per second divided by the square of miles per hour. For example, using 44 ft. per sec., which equals 30 m.p.h., the formula becomes:

$$\frac{v^2}{R} = \frac{44^2V^2}{30^2R} = \frac{2.151V^2}{R}$$

* Add that since the control is 1 then:

$$1 = \frac{2.151V^2}{R} \quad \text{or}$$

$$R = 2.151V^2$$

* Indicate that since the parabola of the vertical curve practically coincides with the radius (R) of the circle then:

$$L = R\Delta = 2.151V^2\Delta$$

where Δ is the central angle in radians.

* Point out that $\Delta = \frac{A}{100}$

where A is the algebraic difference in grades of the sag vertical. Substitute $\frac{A}{100}$ for Δ in the equation $L = 2.151V^2\Delta$. A new expression for L is thus found:

$$L = \frac{2.151V^2A}{100}$$

$$= \frac{AV^2}{46.5}$$

3. Application

* Compute the length of a sag vertical curve for the same problem in which the headlight criteria was used.

$$L = \frac{AV^2}{46.5}$$

$$= \frac{(6)\ (60)^2}{46.5}$$

$$= 463 \text{ ft.}$$

* Note that this is almost as critical as is the headlight distance as far as length is concerned, but in

UNIT II (14.0703-02)

FUNDAMENTALS OF TYPING

Performance Objectives:

Upon completion of this unit the student will be able to type at a rate of 30 wpm/ecol.

Unit Outline:

A. Machine Fundamentals

1. Parts

2. Maintenance procedures

3. Manual and electric typewriters

4. Operation

B. Quality and Performance Standards

1. Speed and accuracy

2. Neatness

3. Language arts

C. Skill Development

1. Keyboard mastery

2. Manipulation of machine parts

3. Speed, accuracy and erasing

D. Typing Applications

Supplemental Teaching Aids:

No suggestions will be made for this unit since free or inexpensive resources are not applicable.

Training Time 70-85 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
VII. General Controls for Vertical Alinement	* Explain that certain general controls must be observed in the design of a gradeline. (Ref. B, pp. 209-211) 1. Use a smooth gradeline with gradual changes always consistent with the classification of the highway and with the character of the terrain. 2. Avoid the roller coaster or hidden dip type of profile. 3. The undulating gradeline involving substantial lengths of momentum grades should be carefully analyzed for their effect on traffic, and if possible avoided entirely. 4. Avoid the broken-back gradeline (two vertical curves in the same direction separated by a short section of tangent grade). 5. On long grades place the steepest grades at the bottom and lighten the grades near the top. An alternative would be to break the sustained grade with short sections of a lighter grade. 6. Reduce grade at the bottom of hills where an intersection occurs. 7. Use a high profile to simplify drainage.
VIII. Combination Horizontal and Vertical Controls	* Emphasize that horizontal and vertical alinements should not be designed independently since the two alinements complement each other. Poorly designed combinations can ruin the good points and aggravate the bad points of each. * Note that horizontal alinement and profile (line and grade) are the most

22631

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

important elements of design. A good balance in their combination increases utility and safety, encourages uniform speed, and improves appearance, almost always without additional cost.

A. General design controls

* Point out that in general design it is usually assumed that the location of a highway is fixed. The only problem remaining is the specific design and harmonizing of the horizontal and vertical alinements. (Ref. B, pp. 212-214)

* State that physical controls acting alone or in combination, determine the type of alinement and include the following:

1. Character of highway justified by amount of traffic
2. Topography
3. Subsurface conditions
4. Existing highway and cultural development
5. Future developments
6. Location of highway terminals
7. Design speed as a check to hold all elements of design in balance

B. Combination controls

* Indicate that horizontal curvature and grades must be balanced and urge that tangent alinement should not be achieved at the expense of steep grades or excessive curves with flat grades.

* State that vertical curvature superimposed upon horizontal curvature gives results that are pleasing to the eye.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

* Mention that sharp horizontal curves should not be introduced at or near the top of a pronounced crest vertical curve since this can create a hazard at night. If this must be done, the horizontal curve should lead the vertical curve and the design should be above the minimum standards.

* Note that a sharp horizontal curve should not be introduced at the bottom of a sag vertical curve.

* Point out the importance of satisfying the passing sight distance requirements on a two-lane highway before attempting a combination of alinements.

* State that both vertical and horizontal alinements should be flattened at all intersections.

* Encourage the design of separate alinements on divided highways whenever possible.

QUESTIONS FOR REVIEW

1. What is the accepted height of eye and height of object when determining stopping sight distance?
2. What is the height of object when determining the passing sight distance?
3. Explain the procedure for checking sight distance graphically.
4. What is the minimum grade which can be tolerated on any pavement?
5. Define critical length of grade.
6. Name and describe four types of vertical curves.
7. What are the necessary controls for the design of a vertical curve?
8. How does a sag vertical curve affect the comfort of a driver?
9. What does A/L signify?

10. Explain what is meant by a measurement of curvature.
11. Explain the theory for the computation of the length of vertical curve with respect to the stopping sight distance.
12. Why is the minimum passing sight distance criteria never used in designating the length of a vertical curve?
13. List four criteria used for the design of a sag vertical curve.
14. Explain why the headlight sight distance criteria is the control used by most states in the design of a sag vertical curve.
15. What is the background for the comfort effect equation?
16. Describe four general controls for vertical curvature.
17. Name seven physical controls which determine the alinement of a proposed highway.
18. Why should a sag vertical curve be as long as the minimum stopping sight distance?

ASSIGNMENT

1. Study pages 244-254 and 259-298 in Ref. B.
2. Find the minimum stopping sight distance on a 1500-ft. crest vertical curve designed for 70 m.p.h. when A is 4 percent.
3. Find the length of crest vertical curve for a 50-m.p.h. design speed when A is 6 percent.
4. Find the length of sag vertical curve designed for 70 m.p.h. when A is equal to 5 percent. Use the headlight sight distance and comfort effect criteria.

INSTRUCTOR'S NOTES

Lesson 10 - Typical Sections and Standard Structure Sheets

OBJECTIVES

- To present the design work necessary to develop typical sections for a project
- To become acquainted with the numerous standard structure sheets used in modern highway design

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Typical Sections	* Define the typical section as a precise schematic diagram of a highway cross section at a particular point or between two particular points.
	* Mention that one typical section might suffice for an entire project but that as many as 40 have been required on a complex arterial highway to avoid the clutter of lines, notes, and figures.
	* Indicate that every possible condition should be shown so that the contractor will be able to construct exactly what was designed in its proper location but avoid using too many typical sections.
A. Variables	* Point out that in showing a cross section variable dimensions may be used to handle more than one situation.
	* Note that alternate factors which may sometimes occur over a given length of highway may also be shown. This is done to avoid making a typical section for every slight change because of topography.
B. Constants	* Emphasize that many items such as pavement and cross slope will remain constant for most of the project.

22635

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
C. Types of typical sections	* State that the typical sections which are shown in the plans will generally consist of five types. 1. Ordinary typical section for the normal portion of the highway 2. Ordinary typical section because of a designed change in the highway 3. Typical section in a rock cut 4. Typical section for intersections 5. Typical sections showing special items such as ditches, pipe underdrains, curbs, and/or gutters, widening sections, and superelevated treatments
D. Pavement changes	* Note that a change in pavement type always requires a different typical section.
II. Typical Highway Cross Section Sheets	* Show a copy of design data sheet 62-5 which consists of 41 sheets of typical highway cross sections approved by the New York State Department of Transportation. (Ref. J)†
A. Purpose	* Emphasize that the purpose of these data sheets is to standardize the use of typical highway cross sections.
B. Nomenclature	* Explain that AASHO structural definitions and terminology are used on typical sections for standardization.
C. Safety program	* Indicate that there have been many changes made for reasons of safety in the cross sections of designs in order to give a wide recovery area for a vehicle forced to leave the pavement.

†Reference citations are shown on page 220.

22636

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Add that this safety program has nullified most of sheet 2 and all of sheets 3-41.
	* Point out that in this lesson sheets 1 and 2 will be used together with sheets 3A and 9A, the latter two being revisions of sheets 3 and 9.
III. Structural Design Terms	* Distribute to each student a print of sheet 1 of D.D.S. 62-5, *Structural Design Terms and Legend.*
	* Note that this first sheet is a key to the other sheets in this series and that the code numbers on the sheet apply to every sheet in the series.
A. Categories of information	* State that the elements of a typical section are divided into two categories: those showing a mathematical relationship or dimension and those indicating the specific item of construction.
1. Dimensional elements (Group 1)	* Indicate that group 1 covers the dimensional elements.
a. Fill slope (No. 1)	* Point out that the legend indicates No. 1 as the fill slope.
	* Note that the slope is a 1 on 2 or a 1 on 4 but emphasize that in May 1967, a change was made which mandates at least a 1 on 5 (preferably a 1 on 6) slope from shoulder to ditch.
b. Original or existing ground (No. 2)	* Trace No. 2 which shows the original or existing ground, commonly called the O.S. (original surface).
	* Compare No. 2 on the left side (fill section) with No. 2 on the right side (cut section).
c. Ditch slope (No. 9)	* Note that this slope is shown as a 1 on 4 from shoulder to ditch but this also has been recently changed to a 1 on 5 (preferably a 1 on 6).

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
d. Cut slope (No. 10)	* Distinguish the cut slope from the ditch slope. Explain that this is the back slope and shown as a 1 on 2 slope.
e. Normal crown slope (No. 12)	* Recall that the normal crown slope is always measured in inches per foot.
f. Design thickness of pavement (No. 15)	* Emphasize that the design thickness is the total dimension for the pavement, whether it is all concrete, part concrete and part bituminous, or separate bituminous courses.
g. Shoulder slope (No. 16)	* Indicate the beginning and the ending of the shoulder slope and point out that the cross slope is now 1 in. per foot.
h. Travel lane (No. 17)	* State that the travel lane is always in the position shown so that a quick inspection will indicate the lane width immediately.
i. Shoulder width (No. 18)	* Note that the dimension line used for the lane width is extended to denote the width of shoulder.
j. Roadway (No. 19)	* Mention that the roadway is the distance covered by the shoulders and pavement.
k. Roadbed (No. 20)	* Point out that the roadbed is the distance between the intersection of the foundation course with the fill slope and/or the ditch slope.
l. Road section (No. 21)	* Define the road section as the portion of a highway included between the top of slope (in cut) and the bottom of the slope (in fill).
m. Theoretical grade line (No. 22)	* Emphasize the importance of the theoretical gradeline since it is the actual finished elevation of the pavement.
	* Demonstrate the simple computations for the elevation differences of all

22638

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	structural end points from the theoretical gradeline and show how these are placed on the typical section.
2. Constructional elements (Group 2)	* Indicate that group 2 covers the constructional elements.
a. Embankment (No. 4)	* Note that the embankment is the roadbed material which fills the space necessary to carry the highway.
b. Shoulder surfacing (No. 5)	* Explain that No. 5 describes the thickness (4 in.) and type of material (bituminous mulch, soil cement color contrasted, or stabilized shoulder) of the shoulder surface.
c. Pavement subbase (No. 6)	* Point out that the pavement subbase indicates the thickness and the type of granular material to be used in the subbase.
d. Pavement base course or courses (No. 7)	* Note that the No. 7 shows a dual composition of pavement base courses.
	* Mention that the base for a bituminous pavement could be made with two base courses and for a bituminous surfaced concrete based pavement the concrete would be the base.
e. Pavement surface (No. 8)	* State that a bituminous pavement surface could consist of one layer but normally a binder course and a top course are used.
f. Shoulder base (No. 11)	* Indicate that the shoulder base is the same material used in the upper layer of the subbase under the pavement.
IV. Pavement Edge Treatment	* Distribute to each student a print of D.D.S 62-5 sheet 2 with details A, B, C, G and H marked superseded.
	* Explain that the treatment of pavement edges is relatively stable, as shown in the details on sheet 2.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Edge with shoulders	* Discuss the treatment given to a pavement edge with shoulders as shown in detail F.
	* State that some of the key numbers are familiar since they were discussed on sheet 1. Point out that three alternatives are shown. 1. Bituminous surface on a concrete base 2. Bituminous pavement 3. Concrete pavement
B. Asphalt concrete curb	* Explain that detail D shows an asphalt concrete curb (barrier type) with all the dimensions necessary for construction.
C. Cement concrete gutter	* Emphasize that detail E (cement concrete gutter) is an excellent example of dimensioning for a typical section.
	* Note that this detail also includes an underdrain which is shown in detail I.
V. Typical Cross Sections	* Add that the typical cross section has been severly altered because of the flattening of the slopes.
A. Dangerous fixed objects	* Mention that the dangerous fixed object (D.F.O.) program is responsible for this major change.
1. Objective of program	* State that the objective of this program is the complete elimination of any object (signs, poles, trees, guide rails) within 30 ft. of the pavement edge.
2. Research data	* Point out that research data indicates that a 30-ft. clear distance from the pavement edge provides a vehicle with an 85 to 90 percent chance for recovery if the slope is flattened to a 1 on 6.

22640

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
B. Two-lane highway	* Distribute to each student a copy of D.D.S. 62-5 3A (dated May 5, 1967). * Emphasize that this is the last official word in designing a typical section.
1. Legend	* State that the numbers used on this sheet are consistent with those described on sheet 1 (nomenclature sheet).
2. Dimensions	* Point out that the dimensions are lettered and listed in table A-1-2-3 under the different classifications of highways. * Use a class 5 (rural) for an example in explaining the values of each dimension.
a. Pavement width	* Explain that the pavement width is designated by the letter A and according to the chart is 12 ft. * Note that every highway now requires a 12-ft. pavement.
b. Shoulder width	* Show that the shoulder width is denoted by the letter B and is 12 ft.
c. Clear distance	* Indicate that the clear distance of 30 ft. begins at the pavement edge and ends at the back of the ditch. * Mention that the typical section on Sheet 3A shows the right side as a half section in earth cut or fill while the left side is a half section in rock.
d. Guide railing	* Show that guide railing is used if the section is in fill and if the slope changes from the flat 1 on 6 to a 1 on 2. * Recall that 2 ft. 3 in. is added to the 30-ft. clear distance whenever guide railing is used.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
e. Pavement cross slope	* Show that the pavement cross slope is marked H and is $\frac{1}{4}$ in. per foot for all classes.
f. Shoulder slope	* Point out that the shoulder slope marked by H (prime) is now 1 in. per foot for all classes.
g. Elevation drop from theoretical grade line	* State that No. 22 is the theoretical gradeline. Demonstrate that the drop in elevation from the gradeline to the outside edge of the shoulder is 12 ft. times $\frac{1}{4}$ in. per foot plus 12 ft. times 1 in. per foot or 15 in. which is indicated by the letter F in the cross section and in the table.
h. Depth of ditch	* Indicate that the depth of ditch is marked by G and that this is measured from the theoretical gradeline.
i. Slope distance	* Note that the slope distance is marked by C and is 14 ft. for class 5-R. This is measured from the outside edge of shoulder to the beginning of the ditch section. * Add that the difference in elevation between these two points is 4 ft. minus 1.25 ft. or 2.75 ft. and since C is 14 ft., the slope of C is approximately 1 on 6. * Show that for Class 7-R the shoulder is 10 ft. and the C distance is 16 ft. This results in a difference of 2.67 ft. between the ditch elevation and the outside edge of shoulder and is approximately a 1 on 6 slope. The typical section calls this a variable slope since the elevation of various points will change due to any superelevated sections.
j. Slope distance in earth fill	* State that the slope from the outside edge of shoulder to the ditch is a positive 1 on 6.

22642

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Note that at the 30-ft. clear distance, the slope may continue on a 1 on 6 or break into a 1 on 4, a 1 on 3, or a 1 on 2 depending on the topography.
k. Slope distance in earth cut	* Mention that again the slope is marked variable since the ditch section, which is begun 4 ft. before the end of the 30 ft. clear distance, alters the slope distance.
	* Emphasize that in an earth cut the back slope leaves the ditch section at a 1 on 4 slope for 10 ft. and then changes to a 1 on 2 slope to original ground.
3. Roundings	* Contrast the new method of rounding by using a vertical curve with the old method of using a horizontal curve.
a. Shoulders	* Point out that an 8-ft. vertical curve is used to round the breaking point of the outside edge of shoulder with the slope.
b. Ditches	* Show that ditches are rounded by using 4-ft. vertical curve.
c. Cut slopes	* Trace the change in cut slopes where a transition is made at the bottom of the ditch to a 1 on 4 slope (4-ft. vertical curve) and from a 1 on 4 slope to a 1 on 2 slope (8-ft. vertical curve).
	* Note that the top of a cut slope is rounded into the original ground with an 8-ft. vertical curve.
d. Slopes on fill	* Indicate that all toes of slopes in fill sections are rounded into the original ground with a 6-ft. vertical curve.
C. Four or six-lane divided highway	* Distribute to each student a copy of design data sheet 9A (dated May 5, 1967).

UNIT III (14.0703-07)

PRODUCTION TYPING

Performance Objectives:

Upon completion of this unit the student will be able to type straight copy at a rate of 40 wpm/ecol in five minutes. She will be able to produce double-spaced report copy of approximately 300 words, with no footnotes, from corrected draft and from hand written copy within 13 minutes. She will be able to produce a mailable business letter of approximately 150 words from corrected draft and from hand written copy within 11 minutes.

Unit Outline:

A. Skill Refinement and Development

1. Keyboard
2. Proofreading
3. Specific areas of improvement

B. Improvement of Production Typing Skills

1. Organization of secretarial work stations
2. Proofreading
3. Corrections
4. The most common typing jobs

C. Applied Production Practice

1. Correspondence
2. Simple statements
3. Tables (boxed and unboxed)
4. Telegrams
5. Cards and labels in quantity
6. Statistical materials
7. Programs, outlines, and similar business papers
8. Envelopes and circulars in quantity

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Compare this typical cross section with the two-lane section just covered.
1. Median under 36 ft. wide	* State that for a median less than 36 ft. wide, that 4-ft. shoulders are used with the cross slope extending at 1 in. per foot for two more feet before changing to a 1 on 6 slope.
	* Point out that important elements in this median are guide railing and a pipe underdrain in the center of the median.
2. Median over 36 ft. wide	* Mention that a median over 36 ft. wide requires no guide railing but it must have pipe under drains for each pavement edge.
D. Superelevated sections	* State that superelevated sections are shown in many different situations on the discarded design data sheets, but until new design data sheets are printed, each design office will have to design each particular section.
1. Shoulder cross slope	* Point out that for a superelevated section the shoulder is continued for 2 ft. on the same plane as the pavement on the high side before cross sloping with the shoulder.
	* Note that the shoulder cross slope begins immediately on the low side.
VI. Standard Structure Sheets	* Explain that the standard structure sheets have been developed by the New York State Department of Transportation in order to standardize certain features of design. (Ref. H)
A. Standardization	* Emphasize that standardization saves time and work whenever a particular item can be used on construction regardless of area, topography, or design class.
B. Method of updating	* Indicate that the standard sheets are a product of the research laboratory

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	of the State Department of Transportation and that the year of each updating is noted before the number of the sheet.
	* Give as an example sheet 67-1, *Cattle Pass, Guide Posts, R.O.W. Markers, Survey Marker.* Point out that this sheet was last revised in 1967.
	* Mention that the second number always remains the same unless another sheet is added.
	* Give as an example sheet 64-45, which was approved in 1964 as *Reticuline Type Grates and Frames.* Note that in 1964 sheet 64-45A was added and sheet 64-45 was retained. Add that in 1964 and 1965 sheets 45B and 45C were added so that at the present time there are four sheets on grates and frames.
C. Content of standard structure sheets	* State that the content of the standard structure sheets covers a wide range and that at present 106 sheets are available.
	* Give a sampling of the available material.
	1. Guide railing 2. Reinforcing for concrete pavement 3. Tools for concrete pavement construction 4. Reinforced concrete pipe 5. Longitudinal and transverse joint supports 6. Concrete cribbing and metal bin type walls 7. Pipe underdrain 8. Culvert backfill 9. Tree planting and guying 10. Sod gutter and strips 11. Railing

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	12. Fencing 13. Delineators 14. Standard closed box culverts 15. Standard bridge details 16. Signs, barricades and barriers

QUESTIONS FOR REVIEW

1. What is a typical section?
2. How is the typical section used in design?
3. How is the typical section used in construction?
4. Name four types of commonly used typical sections.
5. What is the purpose of the design data sheets?
6. Distinguish the ditch slope and the cut slope.
7. What two categories of information make up the typical section?
8. What is the major element of the dangerous fixed object program?
9. What is the usual depth of ditch on a rural highway?
10. Why was the shoulder cross slope changed from $\frac{3}{4}$ in. per foot to 1 in. per foot?
11. Under the newly established criteria when should guide railing be used in the median?
12. How do the standard structure sheets fit in with a design of a highway?
13. Name 10 items detailed on standard sheets.
14. How much distance is added to the 30-ft. clear distance whenever guide railing is used?
15. What is the shoulder treatment for a superelevated section?

ASSIGNMENT

1. Study pages 216-221 and 299-307 in Ref. B.

Lesson 11 - Geometric Auxiliaries

OBJECTIVES

- To understand the importance of geometric auxiliaries in highway design
- To furnish guides and policies relative to the geometric auxiliaries
- To introduce CO GO-90 as a problem-oriented computer language for solving problems on a digital computer

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Geometric Auxiliaries	* Explain that geometric auxiliaries are as important to highway design as the features already discussed. * Note that the previously covered design standards were based on mathematics where as geometric auxiliaries are based on experience. * State that the use of these additional features are usually prescribed by guides or policies furnished by the Department or by the AASHO.
II. Signing	* Emphasize that signing and marking are directly related to traffic volume, highway type, and the frequency of use by visiting drivers. (Ref. B, p. 220)† * Indicate that trunk highways are usually heavily traveled high type roads which have many signs to aid the visiting driver. * Mention that land service highways are lightly traveled low type roads with few signs because many of the drivers are repeat users.

†Reference citations are shown on page 220.

22647

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. Effective signing	* Point out that the physical layout of a highway must be supplemented by effective signing as a means of informing, warning, and controlling drivers. * State that the most important factor for aiding drivers is standardization.
1. Requirements	* Note that any traffic control device must meet the following five requirements (Ref. M, pp. 2-3): 1. Serve a specific need 2. Be easily seen 3. Convey information clearly and simply 4. Command respect of drivers 5. Located to give enough time for response
2. Basic considerations	* Outline the four considerations used to insure that the above requirements are met. 1. Design - size, construction, color, shape, composition, lighting, reflectorization 2. Placement - within the cone of vision of the driver before the situation it controls 3. Maintenance - retention of legibility, soundness of structure 4. Uniformity - aids constant recognition (the same interpretation everywhere), economy in manufacture, installation, and maintenance
B. Classification of signs	* Explain that there are three classifications of signs. (Ref. M, p. 10)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	1. Regulatory signs - notice of traffic laws or regulations
	2. Warning signs - conditions in or adjacent to a highway
	3. Guide signs - route designations, destinations, directions, distances, points of interest
C. Design	* Emphasize that all shapes and colors are standard with only minor changes allowed in the layout of the legend. (Ref. M, pp. 11-12)
1. Shapes	* Point out that the sign shapes are universal in meaning.
	1. Octagon - stop sign
	2. Equilateral triangle (point down) - yield sign
	3. Round - railroad, civil defense evacuation route, state route, or Thruway trail blazer sign
	4. Diamond - hazard sign
	5. Rectangular (long dimension vertical) - regulating sign
	6. Rectangular (long dimension horizontal) - guide sign
	7. Shield - interstate or U.S. highway route sign
	8. Crossbuck - railroad crossing
2. Colors	* Outline the system of colors used in signs. (Ref. M, pp. 12-13)
	1. Regulatory signs, except the red stop sign and the yellow yield sign, are a black legend on a white background. If the sign is larger than 30 by 36 in., it may be black with a white background or vice versa.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

2. Warning signs have a black legend on a yellow background.

3. Guide signs may use white or black for the legend with white, black or green background.

D. Placement

* State that the lateral clearance of a sign is a minimum of 2 ft. from the face of the barrier curb to the near edge of the sign and 14 ft. from the edge of pavement to the near edge of the sign on shouldered highways if the sign posts are made of breakable material.

1. Longitudinal placement

* Note that the longitudinal placement varies with the average approach speeds as follows:

Average Approach Speeds	Advance Posting
Less than 25 m.p.h.	250 ft.
25 m.p.h. to 35 m.p.h.	300 ft.
35 m.p.h. to 45 m.p.h.	400 ft.
over 45 m.p.h.	500-750 ft.

2. Height

* Observe that signs in urban areas must be at least 7 ft. from the crown elevation to the bottom of the sign. In rural areas, they are at least 5 ft. from the crown elevation to the bottom of the sign.

* Emphasize that signs are mounted at right angles to traffic and face the traffic they serve.

III. Markings

* Explain that markings, like signs, control traffic. (Ref. B, p. 221)

* Point out that markings either supplement traffic signs or serve independently to indicate certain regulations or hazardous conditions.

A. Types

* Describe the two types of markings:

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	1. Pavement markings - centerline stripes, lane lines, appropriate striping of no passing lanes on two and three-lane highways, and edge striping
	2. Object markings - painting of piers, abutments, poles, sign posts, guide rails, and curbs
1. Broken line	* Describe the broken line (4 to 6 in. wide) as consisting of 15-ft. line segments separated by 25-ft. gaps and that passing is permitted.
2. Solid line	* Note that the solid line is a warning that traffic should remain in its lane. It is not regulatory and cannot prohibit passing.
3. Barrier lines	* Describe the partial barrier line as consisting of parallel lines, one solid and one broken (for the passing of vehicles from the broken line side) and the full barrier type as consisting of two parallel solid lines which prohibit passing from either direction. * Point out that barrier lines are regulatory.
4. Edge marking	* Note that edge marking is being done on most heavy traffic volume highways.
B. Delineators	* Describe the delineator as a guide marker which is visible in all types of weather. It is composed of a reflector unit, or units, on a steel support which is visible under normal atmospheric conditions from a distance of 1000 ft. when illuminated by the upper beam of standard automobile headlights. (Ref. M, pp. 151-154)
1. Location	* State that these delineators are mounted on the right side of the highway and on the outside of curves. On all curves to the right they are mounted on both sides of the highway.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Types	* State that the one-unit white delineator is used along the right side or on both sides of the highway. The two-unit yellow, or amber, is used along interchange ramp connections, adjacent to acceleration and deceleration lanes and at small openings on divided highways. The three-unit yellow, or amber, is used at special hazard locations.
3. Height	* Mention that the mounting height is a minimum of 4 ft. above the pavement at a point 2 ft. from the edge of the shoulder or at a point 2 to 5 ft. from the face of the curb.
4. Spacing	* Indicate that the normal spacing on a tangent alinement is 200 ft. and on a curved section enough space to allow five delineators to be visible from the right lane. Tables are available for the placement of delineators on curves.
IV. Utilities	* Explain that in New York State private and public utilities are allowed to operate in the legal right-of-way of any State highway under the provisions of the Transportation Law which classifies utilities as common carriers. * Add that the location within this legal right-of-way is prescribed by the Department in a manner which best protects the design, construction, and maintenance interests of the highway.
A. Design	* Point out that the design process mandates relocating all utilities so that consideration may be given to their existing and ultimate location.
B. Municipal utilities	* Note that all municipal utilities are relocated by the State at no cost to the political entity. All private utilities are reimbursed for any relocations only when the utilities are

22652

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	located on property to be appropriated. All other relocations are made at the owner's expense since the occupation of the right-of-way is by sufferance only.
C. Locations	* Emphasize that all pole lines and crossing poles or structures must be behind the ditch line, off the slopes, and as close to the right-of-way line as feasible but under no condition closer that 30 ft. from the pavement edge.
1. Subterranean	* State that waterlines, gas pipelines, or underground telephone conduits cannot be placed under the pavement or under the shoulders except crossings (at right angles to the pavement). If the crossing cannot be placed at right angles, it must be placed as close to a right angle as possible. * Mention that in cities or villages each case will have to be determined on its merits. In general, waterlines, sewers, telephone conduits, and gas pipelines should be placed behind the curb. Sidewalk areas are particularly well adapted for the use of underground facilities.
a. Sleeves	* Point out that a sleeve should be used for any underground conduit crossing under a pavement. This sleeve should extend beyond the out-to-out limits of shoulders but that in a controlled access highway, the sleeve must extend from right-of-way line to right-of-way line since no utilities are allowed on a controlled access highway.
2. Aerial	* State that the clearance from aerial powerlines (because of the summer sag) is usually no problem since the Public Service Commission regulations for the utility companies are much more severe than the Department's.

CONTENT OUTLINE	TEACHING POINTS AND SUGGESTIONS
a. Clearances	* Note that at the present time the Department requires a minimum of 18 ft. of clearance for voltages under 7500 and a minimum of 30 ft. of clearance for voltages over 7500. * Emphasize that all aerial crossings must be at right angles, or as close to right angles as possible. * Indicate that all poles must be a minimum of 30 ft. from the edge of pavement in rural areas and a minimum of 4 ft. from the face of a barrier curb in urban areas.
b. Median use	* Add that a median cannot be used for any utilities.
V. Lighting	* State that highway lighting is a relatively new field. It is used primarily on arterial highways and on rural highways in densely populated areas. Lighting is also used at interchange zones and at channelization areas of rural highways. (Ref. B, pp. 218-219)
A. Type	* Mention that color corrected mercury vapor lamps are generally used for traveled main lines and incandescent lamps may be used on ramps for the contrast effect. * Point out that the mercury vapor lamp, usually at 20,000 lumens, gives out a light made up of greens and blues so red is added (usually neon) to produce a natural effect and is called color corrected. * Indicate that the incandescent lamp, usually at 10,000 lumens, gives out a yellowish white light like the ordinary house-type lamp.
B. Definitions	* State that certain definitions are used in highway illumination work so

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	that design criteria can be established. (Ref. F, p. 2)
1. Luminaire	* Describe the luminaire as a device which directs, controls, and modifies the light source.
2. Candlepower	* Define candlepower as the amount of light that will illuminate a surface 1 ft. distant from the light source to an intensity of 1 ft.-candle.
3. Lumen	* Explain that the lumen is the amount of light which falls on 1-sq. ft. where every point is 1 ft. distant from a source of one candlepower. * Note that a 1 candlepower source of light emits 12.57 lumens.
4. Foot-candle	* Point out that the foot-candle is equal to a luminous intensity of one lumen per square foot. * Mention that all lighting design criteria is based on the average number of foot-candles required on the highway.
5. Uniformity of illumination	* Describe uniformity of illumination as a ratio of average illumination to minimum illumination at any point on the highway. This ratio should not exceed 3 to 1, for major highways and 6 to 1 for residential streets.
6. Lighting standard	* Explain that the lighting standard or pole is a support for the bracket arm and luminaire,and is equipped with the necessary internal attachment for wiring. * Note that the bracket arms are designed in 2, 4, 6, 8, 10, 12, 15 and 20-ft. lengths but caution that the 20-ft. arm must be doubly reinforced because the length tends to set it in motion.

22655

Supplemental Teaching Aids:

No suggestions are made for this unit since supplemental resources are not applicable.

Training Time 60-80 hours

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* State that all lighting standards are designed for a 150 m.p.h. wind
	* Indicate that the new types of lighting standards are constructed with a breakable base for safety and that any object within 30 ft. of the pavement edge must now have a breakable base.
	* Point out that a breakable structure is designed to yield when struck by a vehicle without inflicting serious injury upon the occupants.
	* Mention that only one type of light standard can be used on a project but consideration is given to the local utility company's preference since they will maintain the light standards for the community.
7. Mounting height	* State that the mounting height is the vertical distance between a roadway surface and the center of the luminaire.
	* Add that, at the present time, the mounting height is 30 ft. but it is believed that this height will be increased because a higher luminaire creates less glare and affords a better uniformity ratio.
8. Spacing	* Define spacing as the distance in feet between successive light standards and it is considered to be one-sided or staggered.
	* Mention that if opposite spacing is used, twice as much illumination is available.
9. Overhang	* Describe the overhang as the distance from the light standard to the pavement edge.
10. Coefficient of utilization	* Note that the coefficient of utilization is the ratio between the

22656

CONTENT OUTLINE

C. Spacing of luminaires

1. Equation for spacing

TEACHING POINTS AND TECHNIQUES

total light generated within the luminaire and the amount of light which actually falls on the area to be lighted.

* Emphasize that the spacing of luminaires is usually the required information for any design.

* Write the equation for spacing of luminaires on the chalkboard and explain the factors involved.

$$S = \frac{(MLL)(U)(LMF)}{(Avg.\ F)(W)}$$

where S = longitudinal spacing of luminaires

MLL = mean lamp lumens of the luminaire which is less than the rated value and is found on the manufacturer's rating sheet.

U = coefficient of utilization which must be secured from a graph for the particular type of luminaire being used. The graph uses the ratio of the effective width of pavement over the mounting height for the abscissa and the coefficient of utilization as the ordinate. (Ref. F, p. 11, figure 9)

LMF = luminaire maintenance factor is a manufacturer's figure (usually about 90 percent).

Avg. F = average foot-candles is the design criteria information specified by the design office.

W = width of roadway

CONTENT OUTLINE

2. Application

TEACHING POINTS AND TECHNIQUES

* Find the spacing required between luminaires in order to maintain an average illumination level of 1.5 foot-candles where the road width from curb to curb is 50 ft., mounting height is 30 ft., and the overhang is 4 ft. The luminaire is 400 watts, 24,000 initial lumens (20,200 mean lumens)—a type III distribution with a maintenance factor of 90 percent. (Ref. F, pp. 10-11)

* Point out that the coefficient of utilization must be found first for the area to be lighted from both the street side and from the house side.

$$\text{Ratio (street side)} = \frac{50 - 4}{30} = \frac{46}{30} = 1.53$$

$$\text{Ratio (house side)} = \frac{4}{30} = 0.13$$

* Distribute charts of the utilization curve for Illuminating Engineering Society (I.E.S.) type III distribution luminaires which are supplied by the major lamp manufacturers.

* Use the chart in figure 9, (Ref. F, p. 11) and show that 1.53 is located on the abscissa, that a vertical line intersects the street side curve, and that a horizontal line intersects the ordinate at 0.39.

* Duplicate this maneuver for 0.13 on the abscissa and find 0.04 on the ordinate.

* Indicate that the coefficients 0.39 and 0.04 become the total coefficient of utilization or 0.043.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Substitute in the equation: $S = \frac{(MLL)(U)(LMF)}{(Avg.\ F)(W)}$ $= \frac{(20,200)(0.43)(0.90)}{(1.5)(50)}$ = 104 ft. staggered spacing or 52 ft. opposite spacing
D. Design criteria	* Mention that in New York State our standards allow 1 foot-candle of light intensity on the main traveled lanes, which is increased by 15 percent when the surface is covered with bituminous material, and increased another 30 percent in an interchange area.
	* Explain that ramps require 0.8 foot-candles on concrete, increased by 15 percent for a bituminous surface.
1. Location	* Note that the locations of light standards are based first on safety (offset from the pavement edge) and second on light intensity.
a. Ramps	* Emphasize that for ramps on tangent alinement or on 1500-ft. radius curves luminaires may be placed on either side. If the curve is sharper than 1500 ft. and the lighting is placed on the outside of the curve, then the spacing must be 0.7 of the spacing required on the tangent. If the lighting is placed on the inside of the curve, the spacing must be 0.55 of the spacing required on the tangent.
	* State that when the luminaires are placed on the right side of the ramp in the direction of travel (with no curbs or with mountable curbs) there will be a 10-ft. minimum clear distance between the pavement edge and the face of the light standard base. If the luminaires are placed on the left side of the ramp (in the direction of travel), there will be

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	an 8-ft. minimum clear distance from the edge of the pavement and the face of the light standard base.
2. Traveled lanes	* Indicate that the minimum clear distance between the curb face and the face of the light standard base must be 4 ft. but that 6 ft. is more desirable. On pavement without curbs a 12-ft. minimum clear distance is required.
VI. Landscaping	* Emphasize that landscaping makes the highway look good and prevents erosion. (Ref. B, p. 216)
A. Erosion control	* Note that erosion is controlled to a considerable degree by the cross-section design, proper drainage, and appropriate landscaping. * Mention that erosion and maintenance are minimized largely by the use of: 1. Flat side slopes, rounded and blended with the terrain 2. Ditches and channels designed with due regard to width, depth, slopes, alinement, protective treatment and type of runoff 3. Interceptors located and spaced with erosion control in mind 4. Proper facilities for ground water interception 5. Dikes, berms, and other protective devices 6. Protective ground cover and plantings and light asphalt spraying to hold straw cover together while the grass is growing
B. Landscaping control	* State that in landscape design the following should be considered:

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	1. Removal of trees, the protection of trees left in the clearing, and grubbing procedure 2. Tree care, such as pruning, painting of tree wounds, tree feeding, and spraying 3. Selective thinning for highway construction through wooded areas 4. Use of herbicides 5. Seeding, sprigging, sodding of grass, and jute mesh 6. Fertilizing and mulching 7. Planting of suitable and pleasing trees and shrubs for erosion control, beauty, traffic guidance, and screening * Point out that screening assists in reducing headlight glare and sounds and also prevents snow drifting on highways.
C. Roadside parking areas and scenic overlooks	* Indicate that there is a trend of establishing roadside parking areas to let drivers rest and also scenic overlooks designed to beautify the area or to provide the opportunity to enjoy a view. * Note that areas are placed at intervals of 25 to 30 miles and are always accessible from the right-hand traffic lane. * Add that an island should separate the through traffic from the parking pavement and that acceleration and deceleration lanes should lead traffic in and out of the parking area.
1. Types	* Mention that two types of areas are used:

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. A safety turnout with trash cans and shade trees	
2. A more elaborate development with drinking water, fireplaces, toilet facilities, and telephones	
2. Size	* State that each area, regardless of type, should be about 800 ft. long and 100 to 400 ft. deep, exclusive of the approaching lanes.
VII. Right-of-Way	* Emphasize that the designation of an appropriate right-of-way for a given project is a design function.
	* Note that the standards chart specifies the amount of right-of-way necessary for each class of highway.
	* Point out that careful consideration is given to the acquisition of the right-of-way in an urban area.
A. Determination of taking lines	* Mention that the determination of the taking line begins with the placement of the toes and tops of slopes on the plan.
	* State that this information is taken from the cross-section sheets.
1. Grading line	* Designate that the line connecting the toes (circles for symbols) or tops (triangles for symbols) is the grading line and that at least 15 ft. more of right-of-way should be appropriated.
2. Exceptions	* Indicate that exceptions must be made when a property line is 10 ft. or 20 ft. away from the grading line.
B. Types of appropriation	* Relate that property on existing highways is appropriated either in fee (with or without the right of access), as a permanent easement, or as a temporary easement.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. Fee with the right of access	* Point out that a fee title with the right of access can be appropriated anywhere but positively must be used on an existing highway.
	* Note that this property now becomes lands of the State.
2. Fee without the right of access	* State that a fee title without right of access is usually taken when the highway is on a new location.
	* Emphasize that this is a condition where the right of abutting owners to access in connection with a highway is fully controlled by the State.
	* Describe a controlled access highway as one which may be fenced.
3. Permanent easement	* Indicate that the permanent easement is a perpetual privilege to the State while the original owner still possesses title.
	* Point out that these easements are used when work such as drainage, maintenance of slopes, grading, and maintenance of bridges is necessary.
4. Temporary easement	* Explain that a temporary easement is a short term loan of a piece of property (usually a period of time during construction) so that a certain type of work may be carried out. This easement is relinquished after the contract is executed.
VIII. CO GO	* Describe CO GO as a problem-oriented computer language and programing system for solving geometric problems in civil engineering on a digital computer. (Ref. N)
	* Emphasize that this program has become the most useful engineering data processing tool available in our department to date.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

1. Use for the *Start* command *Sample COGO Problem.*

2. Clear positions 1 to 999 of the X and Y coordinate tables.

3. Store the coordinates (Y = 5000, X = 2000) of point 51.

4. From point 51 locate point 22 at a distance of 2236.07 ft. and an azimuth of 116°34'00". Output and store the coordinates of point 22.

5. From point 22 locate point 14 at a distance of 2828.67 ft. and a bearing N 45°15'39" (NE = quadrant 1). Output and store the coordinates of point 14.

6. Include *Comment Point 14 on Main Street* in the output.

7. Backsight on point 22, turn an angle at point 51 to locate point 97 at a distance of 3605.09 ft. and an angle 82°27'00" (counterclockwise). Output and store the coordinates of point 97.

8. Inverse between points 97 and 14 and output the distance and bearing of the line between the points. Store the bearing in position 97 of the table of bearings.

9. Compute and output the clockwise angle at point 97 from point 14 to point 51 and store in position 97 of the table of angles.

10. Store the coordinates (Y = 8000, X = 6000) of point 6.

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

11. Locate point 42 by intersecting the line between points 51 and 6 with the line between points 14 and 97. Output and store the coordinates of point 42.

12. From point 51 in the direction of point 42 locate point 35 at a distance of 1156.21 ft. Output and store the coordinates of point 35.

13. Calculate and output the distance between points 51 and 42 and store this in position 20 of the table of saved distances.

14. Calculate, output, and store as point 342 in the coordinate table the intersection of the arc whose center is point 51 and whose radius is stored in position 20 of the table of saved distances with the line defined by points 14 and 22. Of the two possible answers (a line intersects a circle twice except at the point of tangency) the point to be used is the one closest to point 14.

15. Compute the area enclosed by the straight line sides formed by points 35, 42, 342, 22, and 35 and store in position 15 in the table of saved areas. Output the area in square feet and acres, and also output the distances, azimuths, and bearings for each side of the enclosed area.

16. Include *Comment Land Parcel Owned by J. Smith* in the output.

17. Calculate and output the area formed by the chord between points 42, 342, and the ard getween the same 2 points. The radius of the

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

arc is stored in position 20 of the table of save distances. Also calculate and output the chord length and arc length. Then add the calculated area to the area previously computed by the *Area* command and output the cumulative area with the segment included and store in position 16 of the table of saved areas.

6. Output

* Distribute prints of the output or answer to the sample problem (figure 21). (Ref. N, p. 13)

* Explain that with the output each input command is also reproduced.

* Note that the time of processing the problem and the cost is given at the bottom of the output sheet.

* Point out that the in-out time for this problem was 5.1 seconds and the cost was 15 cents.

7. Future use

* Indicate that at the present time 85 percent of the mathematical work in the design office is being done by computer.

* Emphasize that any use can be made of this program. An individual's ability and resourcefulness are the only limiting factors.

* Characterize the CO GO-90 as a device used to ease the communication barrier between the highway engineer and the computer.

QUESTIONS FOR REVIEW

1. What is the aim of signing?

2. Name four requirements of a traffic control device.

3. Describe a regulatory sign.

4. What does a solid yellow line on the centerline of a highway signify?

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
A. CO GO-90	* Explain the CO GO-90 as a language system by which an engineer, without programing experience, can translate a problem into the language of the IBM 1650 or the Burroughs B5500 digital computers.
B. Operation	* Point out that the digital computer can solve any problem which can be conceived and programed but that some difficulty is sometimes encountered in the mechanics of programing. * Note that the common, lengthy, error-prone type of problem can now be tramsmitted by telephonics directly to the computer center.
1. Typical problems	* Give examples of typical problems which can be solved: 1. Control, land, and right-of-way surveys 2. Highway and interchange design 3. Construction layout 4. Bridge geometry
2. Time element	* Mention that a program for a given problem can be written in minutes and the problem can be of any length since it is not limited by the size of the computer memory.
3. Cost	* State that the cost is relatively small because of the speed of the computer.
4. Programs	* Indicate that a new program is written for every problem and then discarded when the problem is solved. * Point out that the programs are written by using a series of commands which describe basic civil engineering operations such as alinement used to calculate the horizontal alinement of a curve.

22664

CONTENT OUTLINE

C. Sample problem

1. Sketch

TEACHING POINTS AND TECHNIQUES

* Use a sample problem to illustrate the structure of CO GO-90 commands. (Ref. N, pp. 6-14)

* Draw figure 19 on the chalkboard.

DIAGRAM OF SAMPLE COGO-90 PROBLEM

FIGURE 19

* Note that the known quantities are:

1. The coordinates of point 51 and 6
2. The length and azimuth of the line 51-22
3. The length and bearing of the line 22-14

22665

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	4. The length of line 51-97 and the counterclockwise angle at 51 from 22 to 97
	5. The length of the line 51-35
2. Desired results	* State that the following results are desired:
	1. The coordinates of all points
	2. The length and bearing of the line 14-97
	3. The angle at 97 from 14-51
	4. The area of the parcel bounded by side 35-42, arc 42-342, side 342-22, and side 22-35 and the length and azimuth of the sides of the parcel
3. Input program	* Note that the input program is placed on a special form (EDP 98), called a coding form.
	* Distribute to each student prints of the coding form with the above problem programed (figure 20). Ref. N, p. 9)
4. Transmission of the programing	* Indicate that the transmission of the programing is done by an operator on a teletypewriter transmitter.
a. Transmission tape	* Show examples of a transmission tape which is punched out, checked, and transmitted.
b. Transmitter	* Exhibit pictures of the transmitter and point out its complexities but reiterate that it merely transmits the problems to the computer in Albany.
5. Instructions to the computer	* State that each line of the input is a command for the computer.
	* Have the students follow the commands for the sample problem on their copies of figure 20 which is found on the following page.

UNIT IV (14.0703-11)

SHORTHAND PRINCIPLES

Performance Objectives:

Upon completion of this unit the student will be able to: (1) transcribe, with at least 95% accuracy, familiar material dictated at 60 to 80 wpm for 3 minutes or at 50 to 70 wpm for 5 minutes. (2) transcribe with at least 95% accuracy, unfamiliar material dictated at a median rate of 60 wpm for 3 minutes.

Unit Outline:

A. Introduction to Shorthand

1. Abilities needed for development of shorthand skill.

2. The nature of shorthand

B. Reading and Construction of Shorthand Words and Abbreviations

1. Symbolic systems

2. Abbreviated alphabetic systems

C. Dictation

1. Familiar material practiced and previewed

2. Familiar material previewed

3. Unfamiliar material previewed

D. Spelling

E. Vocabulary

F. Punctuation

G. Pre-transcription Training

1. Oral transcription

2. Handwritten transcription

3. Typewritten transcription

5. To what extent are utilities included in a highway design?

6. Where is the best location for subterranean utilities in an urban highway design?

7. What is the minimum edge distance from the pavement edge to the nearest utility structure?

8. What is a foot-candle?

9. Why can an aluminum light standard be tolerated with an edge distance of 12 ft.?

10. What is the coefficient of utilization?

11. How does proper landscaping prevent erosion?

12. Name five functions of landscaping control.

13. What single item basically controls the taking line of property for a new highway?

14. Differentiate between the four common types of property appropriations.

15. What is the function of the CO GO-90?

ASSIGNMENT

Study pages 312-331 in Ref. A.

INSTRUCTOR'S NOTES

22672

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
F. End of second phase	* State that the work up to this point completes the second phase of design. * Add that the contract tracings are now begun.
V. Contract Sheets	* Note that the third phase begins with the completion of all the design data on the contract sheets. * Exhibit several contract sheets and explain that they contain all the design information necessary for construction of a given project. Use plans of a current design.
A. Orientation section	* Indicate that the orientation section contains data which identifies and locates the project.
1. Title sheet	* Point out the location map, which is a small scale map showing the geographic site of the work area. * Explain the use of the identification and signature blocks on the title sheet.
a. Official designation	* State that ample space must be furnished for the project title, names and numbers of the highways involved, a copy of the State map, and a list of the required standard sheets. * Add that these are placed on the title sheet by the main office along with the required signatures.
b. Traffic data	* Point out the block which indicates the projected traffic counts with a notation for the design hourly volume (DHV) and the average annual daily traffic (AADT) and the year into which it has been projected.
2. Index sheet	* Observe that a contract of any size should have an index sheet to simplify locating any particular sheet or detail.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
3. Table of maintenance and jurisdiction	* Explain the procedures for assigning jurisdiction of maintenance for certain portions of the highway such as abandoned sections, city portions, town portions, and highways on new alinement. * Emphasize that since this is a legal record, stationing should be very carefully computed and checked.
4. Item summary	* Mention that on any project it is advisable to have an item summary sheet, which shows each item with the actual or neat quantity and the proposed quantity in tabular form.
5. Scale plan and profile	* Indicate that the 200-ft. scale plan and profile is the next category of information in the contract plan and mention that this is used strictly as an aid for orientation.
B. Data section	* Advise the class that the data section contains the research background of the contract.
1. Typical sections	* Show that each typical section is placed in the contract plans in the order in which it is used. * Add that any general notes are also placed on the typical section sheets.
2. Tables and charts	* Describe briefly the system used in formulating the following listings: 1. Earthwork summary sheet 2. Unclassified excavation 3. Trench, culvert, and bridge excavation 4. Table of lengths 5. Bench marks 6. Guide railing 7. Pipe underdrain 8. Curbs 9. Drainage structures 10. Gutters 11. Grouted riprap 12. Driveways 13. Stone channel protection

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	14. Drop inlet and manhole locations 15. Intersections 16. Right-of-way monuments 17. Chain link fencing 18. Sign text data 19. Barricades 20. Design curve data with P.I. locations 21. Sidewalks 22. Utilities (waterlines, hydrants, water valves, valve boxes, etc.) 23. Superelevation chart or table * Distribute prints containing some of the listed items. These may come from different jobs and need not all be similar.
3. Special details	* Exhibit the sheets which cover detailed drawings of specials like drop inlets, manholes, ditching, berms, gutters, curbs, steps, medians, and soils apparatus
4. Special culverts	* Mention that the design of special culverts is shown on separate sheets which also includes the items and quantities to be used. * Note that the culverts are identified by a number, a centerline stationing, skew, type, and size. Channel inprovement profiles and details such as strutting of metal pipes are also included.
a. Concrete cribbing and bin-type retaining walls	* Indicate that a complete detailing of concrete cribbing and retaining walls is required for the foundation plans, elevations, and side views, and also a list of materials to be used.
5. Roadside development	* Point out the sheets which cover landscaping and developing of slopes, malls, parking areas, and islands with respect to applying topsoil, mulching, seeding, planting trees, and controlling erosion.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	to the base line for field use. The points of curvature (P.C.) and the points of tangency (P.T.) should also be tied in, at least for design records.
C. Equalities	* Note that the centerline is also properly equalized whenever it drifts far from the base line or whenever an existing stationing is to be continued.
	* Describe the operation of equalizing to the base line and mention that this procedure should be repeated only a limited number of times.
D. Records	* Mention that all centerline computations and checksheets are recorded and filed.
E. Profiles	* State that any hold controls such as railroad intersections, bridges, other highways, rock conditions, and potential drainage problems are marked for further investigation.
	* Point out that the grade line is now computed for verticle curvature. Also any equalities in elevation must be accounted for.
F. Contour maps	* Indicate that a large scale (usually 1 in. = 20 ft.) contour map is prepared for any area of a bridge site.
	* Note that all centerline information is shown on this topographic map and that it is given to the bridge section in the design office.
III. Cross-Section Design	* Review the process of plotting the survey level notes on cross-section paper and describe the method used in placing a template of the typical section on the cross-section sheet. (Ref. A, pp. 331-336)
	* Use a cross-section sheet with at least three stations.

22674

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Demonstrate how the template is placed on the cross-section sheet.
A. Ditches	* Point out that all ditches are shown on the cross sections.
B. Slopes	* Demonstrate how the toes and tops of slopes are located on the cross section and show how the information is plotted on the plan.
	* Designate the plotting of these points as the plotting of the grading line.
C. Drainage	* Note that the drainage is designed next and the drainage sheets drawn up.
	* Indicate that drainage design comprises culverts, lateral runoff pipes, underdrains, storm sewers, drop inlets, catch basins, manholes, headwalls, and endwalls.
D. Earthwork quantities	* Emphasize the importance of measuring the quantity of earthwork between stations and briefly describe the process.
IV. Layout Design	* Point out that at this stage the layout work of design begins with the location of the new right-of-way line.
A. Mapping of property	* Mention that the mapping and computing of the required appropriations of property is the next step.
B. Intersections	* Note that all intersections are designed individually with a workup detail sheet for each one.
C. Field inspections	* Emphasize that before more design work can be placed on paper, additional field inspections must be made to verify and supplement the original survey notes so that the design of drainage facilities, driveways, sidewalks, cattle passes, and utilities can be simplified.

22675

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
1. New information	* Indicate that any new information should be immediately fitted to the line and grade and to the templates of the typical sections. * State that most changes made at this time are usually minor.
D. Lateral cooperation	* Add that lateral cooperation with the other sections of the Department is most important at this stage. * Emphasize that prints of the alinement, complete with tops and toes of slopes, are furnished to the landscape architect, utility engineer, soils engineer, and to the resident maintenance engineer for study.
E. Details	* Explain that the work of detailing begins after the layout is completed but indicate that the following list of items is always a part of any design: 1. Items of construction 2. Earthwork details 3. Special drawings 4. Bench marks 5. Buildings 6. Table of lengths 7. Sight distance graphs 8. Superelevation tables 9. Item details * Many other items will be mentioned when the contract plans are discussed.
1. Items of construction	* Note that a list of all the items necessary for construction is now prepared with special attention given to nonstandard items.
2. Earthwork details	* Discuss the computation and compilation of the earthwork quantities and show that these figures will make up an earthwork summary sheet.
3. Special drawings	* Emphasize that special drawings must be made for any item which cannot be

22676

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	found on the standard sheets such as curbs, sidewalks, gutters, manholes, drop inlets, or any appurtance which is considered to be a special item.
	* Add that when these special items can be altered to conform to the standard sheets, no detailing is necessary and the standard sheet is quoted by number.
4. Bench marks	* Indicate that a complete list of bench marks, in order of stationing, is prepared.
	* State that the contractor should be notified about any U.S.G.S. bench marks in the area.
5. Buildings	* Bring out the fact that a list of all the buildings to be demolished must be prepared for insertion in the plans and for use by the Lands and Claims Section of the Right-of-Way Department.
	* Point out that the buildings must be numbered and located by station offset.
6. Table of lengths	* Emphasize that every foot of new pavement must be accounted for in a Table of Lengths which is in tabular form and in geographical order.
7. Sight distance graphs	* Explain the necessity for checking the minimum passing sight distance and the minimum stopping sight distance so that the profile can be adjusted accordingly.
	* State that the graph information is now placed on the profile.
8. Superelevation tables	* Indicate that any superelevation tables necessary for construction should be made for inclusion in the plans.
9. Item details	* Note that all items are analyzed for quantity and this quantity, with the method of computation, is placed on the detail sheets.

22677

Lesson 12 - Sequence of Design (Second, Third, and Fourth Phases)

OBJECTIVES

- To introduce sequential steps necessary to prepare the second, third, and fourth phases of the design procedure
- To become acquainted with the procedures and methods of consolidating data.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Design Work	* Explain that the second phase begins with the actual design work which covers all of the operations and information required by the contract sheets.
A. Adjustments	* Note that any adjustments which may have been recommended are now incorporated in the design.
B. Working plans	* State that several prints are made of the 50-ft. (or 20-ft.) scale plan for use in the different design operations.
C. Typical section	* Mention that a detailed sketch of each typical section to be used in the project is drawn and the items to be used in construction are arrowed to the proper position.
II. Centerline Control	* Emphasize that the next step in the design is involved with the mathematical control of the centerline. (Ref. A, pp. 318 - 331)†
A. Orientation	* Add that the centerline is now mathematically tied both in direction and in length.
B. Ties	* Point out that all of the points of intersection (P.I.) are positively tied

†Reference citations are shown on page 220.

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

MICROCOPY RESOLUTIO
NATIONAL BUREAU OF ST

ON TEST CHART
TANDARDS-1963-A

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
6. Delineators	* Note that the number and type of delineators required are identified by code on a line type diagram. * State that a layout plan in a schematic form is generally made using the 200-ft. scale.
7. Location plan for signs	* Display a location plan for signs and explain that the code is shown in the table of sign text data.
8. Traffic signalization	* Mention that the traffic signalization sheets consist of layout plans of intersections which show the locations, phase controls, pad locations, and design details of the traffic control equipment.
9. Lighting	* Explain that a set of layout design plan sheets are used for lighting plans. These sheets are merely skeletal drawings showing only the more important features such as lanes, sidewalks, curbs, intersections, centerline, base line, and a few identifying or orientating objects. * Note that a detailed sheet showing the design and specifications of light standards, pull boxes, conduit, and foundations precedes the layout sheets.
C. Design section	* Indicate that the next group of sheets contain the layout design of the new highway.
1. Plan	* Mention that the highway design is shown on either a 50-ft. or a 20-ft. scale plan together with its appropriately scaled profile. * Point out that the layout of the new design indicates all of the existing topography and all of the new elements to be constructed.
2. Drainage sheets	* State that if the layout is complex or crowded, it may be expedient to

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	follow each layout sheet with a sheet indicating drainage details only. * Add that the drainage sheet shows the drainage notes and diagrammatic legends. Point out the confusion which could occur if the drainage data and diagrams were superimposed on the design layout sheet.
3. Bridge design	* Note that any bridge to be constructed is a self-contained unit of separate sheets. This group of sheets is attached to the design plan for the highway (preferably at the end). * Point out that the bridge plans are tied in to the highway plans by centerline stationing and a skew angle.
4. Standard sheets	* Indicate that any standard work included in the contract is done according to its particular standard sheet. * Review that all the standard sheets used are listed on the title sheet and are automatically a part of the contract plans.
5. Large scale plans	* Emphasize that the large scale plans should be checked for the following information (Ref. G, pp. 11-1 to 11-5): 1. Scaling of stationing 2. Tie points, centerline distances, azimuths, and north points 3. Existing highway boundaries 4. Name and direction of creeks or rivers 5. Property lines, fences, corners, and monuments 6. Base line transit points and ties 7. Trees, buildings, sidewalks, driveways, utilities, culverts, and political subdivisions. 8. Names of property owners 9. Limits of work 10. Curve data and P.C. and P.T. locations

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	11. Equalities 12. Bench marks
6. Typical sections	* State that the typical sections should be checked for the following information: 1. Dimensions 2. Theoretical gradeline 3. Limits of use by stations 4. Variables with station control 5. Item titles and numbers 6. Cross slopes of the pavement, shoulders, and slopes
7. Profile	* Note that the 50-ft. (or 20-ft.) profile should be checked for the following information: 1. Scaling 2. Datum 3. Control points 4. Gradients 5. Vertical curve data 6. Invert and ditch end elevations 7. Gutter and ditch grades 8. Creek profiles 9. Profiles of intersecting highways
VI. Report on Design and Estimate	* Explain that the fourth and last phase of design is the report which is a collection of all the pertinent information relating to the design. This report will be examined in a later lesson.
A. Special notes and specifications	* Emphasize that all special notes and special specifications are written in a report-like description. Be careful of contradictions, ambiguities, and impossibilities.
B. Estimate	* Indicate that the next step is the preparation of the estimate with prices based on actual or neat quantity values.
1. Cost analysis	* State that a cost analysis is made of those items which are secured locally.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
C. Final check	* Note that in the final check, all tracings are oriented in the proper order and checked for other sheet references and match-line references on other sheets.

QUESTIONS FOR REVIEW

1. What is the first operation after line and grade have been approved?
2. Why is a template placed on every cross section?
3. Why is it necessary to make a field inspection before too much design work is completed?
4. Name four departments that require prints of the alinement of a new design as soon as the grading lines are established.
5. Why does the bridge section require a large scale contour map of a potential bridge site?
6. What is the table of maintenance and jurisdiction?
7. What is the purpose of a 200-ft. scale plan and profile?
8. Describe a roadside development sheet.
9. List 10 items which should be checked on the large scale contract plans.
10. What is the report on design and estimate?

ASSIGNMENT

Study pages 342-347 and pages 349-361 in Ref. A.

INSTRUCTOR'S NOTES

Lesson 13 - The Engineer's Estimate

OBJECTIVES

- To become acquainted with the procedures necessary to obtain data for an estimate
- To provide the nomenclature and mode of measurement for the typical items which appear in a design

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Preliminary Estimate	* State that the preliminary estimate is made to determine the approximate cost of a particular design of a proposed project.
A. Basis	* Note that since this estimate is based on incomplete information and on inconclusive evidence, the cost of each item should be amply assessed. (Ref. A, pp. 342-347)†
B. Source of information	* Add that all the available information is usually derived from a reconnaissance survey.
II. The Engineer's Estimate	* Define the engineer's estimate as an analysis of the estimated quantities of work which is used as a basis for financing the improvement and for comparison with the contractors bids.
A. Unit price contract	* Emphasize that the estimate is geared to a unit price contract and that the contractor is paid according to the unit price.
	* Observe that no matter how precisely the project is designed, there always

†Reference citations are shown on page 220.

22685

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

1. Item 1 - clearing and grubbing (Ref. K, pp. 293-295)

2. Item 1W - furnishing water equipment (Ref. K, p. 296)

3. Item 6E - engineer's office (Type A, B, or C) (Ref. K, pp. 313-316)

4. Item 76 - maintenance and protection of traffic (Ref. K, pp. 482-489)

5. Item 77 - temporary structure and approaches (Ref. K, pp. 489-490)

6. Item 81 - dismantling and storing existing superstructures (Ref. K, p. 496)

7. Item 81A - removing existing superstructures (Ref. K, p. 497)

8. Item 81B - dismantling and removing existing superstructures (Ref. K, p. 497)

9. Item 87 - furnishing equipment for driving piles (Ref. K, pp. 521-522)

10. Item 88 - load tests for soils (Ref. K, p. 522)

11. Item 88P - load tests for piles (Ref. K, p. 522)

12. Item 114 - railroad protection (Ref. K, p. 561)

13. Item 116 - stakeout survey (usually at about 1 percent of the estimate) (Ref. K, pp. 563-565)

14. Item 120 - disposal of buildings (Ref. K, p. 567)

15. Item 120R - relocating buildings (Ref. K, pp. 569-571)

22639

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	are variables which the bidding does not reflect.
B. Detail sheets	* Distribute prints of a completed detail sheet and explain that this is a quantitative summation of each item in the contract and that this information is placed on the estimate sheet.
1. Order	* Note that each item to be used is listed in numerical order. If certain items are lettered, such as 14A, 14B, then the items are placed alphabetically within the number group.
2. Units	* Emphasize that each unit is measured in a certain manner and that payment for an item is based on this method of measurement.
3. Reference	* Indicate that each item is referenced by stations, by reference to another item, and by reference to a sheet of tables. Use the following examples: 1. Item 11-24, 200 ft. of round corrugated metal pipe, 24 in. diameter, 12 gage from station 10 + 62 to station 12 + 82 2. Item 13-20, cast iron pipe, 20-in. diameter, 72 ft. (Note 17U from table of Utilities) 3. Item 46, concrete foundation for pavement, 1000 square yards of pavement taken from the computation of Item 8, preparing fine grade. The amount of concrete required is 1000 square yards times 8 in. (thick) divided by 36 in. (sq. yds. to cu. yds.) or 222.2 cu. yds. but say 225 C.Y.
4. Rounding	* Emphasize that rounding of amounts for estimating is no longer used in the New York State Department of Transportation but that some other

22686

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	departments and private consulting engineers still use rounding.
	* Explain that the actual or neat quantity which is required by the design is noted and then this neat figure is rounded in accordance with the amount of probable change which could occur in the item.
	* Mention that items which tend to be uncertain (such as earthwork) were often rounded from 15 to 25 percent. Positive items were rounded only from 2 to 5 percent.
a. Present method	* Point out that at the present time a neat quantity is computed and the figure is rounded to the next highest figure in order to simplify the mathematics in determining the cost.
	* State that almost all quantities (with exception of large single items like signs and light standards) have figures which end in 5 or zero.
(1) Advantages	* Indicate that the present method of handling quantities has been adopted for financial reasons.
	* Emphasize that as soon as a contract is let for bidding, the amount of the bid is set aside by the State Comptroller to pay the contractor when construction is finished.
	* Show that if an estimate were rounded excessively, the bid would be larger than necessary since it would involve money for quantities not really required, and despite the fact that the total sum is not used, it cannot be used elsewhere.
(2) Examples	* Note that if structural steel were computed to be 5,444,173 lbs. (neat), it would be listed in the plans as 5,445,000 lbs. (proposed).

22687

CONTENT OUTLINE	TEACHING ~~POINTS~~ AND TECHNIQUES
	* Add that if 1591 cu. yd. of concrete were computed, it would be shown as 1591 C.Y. (neat) and 1595 C.Y. (proposed).
III. Measurement of Items	* Explain that a definite measurement must be assigned to every standard item quoted in the specifications book and to any special item required for a particular function.
	* Emphasize that types of measurements are rigidly adhered to so that a comparative picture between two projects may be made regardless of the elapsed time between them.
	* Mention that a consistent pattern of measurements is helpful to the designer, the estimator, and the contractor.
	* State that since the cost of living rises approximately 5½ percent per year, it is of little value to distribute lists of past bid prices.
	* Point out, however, that whenever a certain item is discussed, its average price of the year before will be stated.
	* Note that this will make the item estimate more realistic and assure a better perspective of the design picture.
A. Items accounted for by a lump sum	* Define a lump sum item as one which includes the cost of furnishing all materials and/or labor and/or equipment necessary to complete the work.
	* Indicate that only one price is used, which is the estimated cost for the total execution of the item.
	* List and discuss the following standard items which are accounted for by a lump sum:

22638

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

the maximum payment lines as shown on the plans. (Ref. K, p. 300)

7. Item 2UF - underdrain filter: paid for by the number of cubic yards measured in place between the maximum payment lines as shown on the plans. (Ref. K, pp. 300-301)

8. Item 3 - subbase course, granular material: paid for by the number of cubic yards of compacted material between the payment lines as shown on the plans (Ref. K, pp. 301-303)

9. Item 4 - subbase course, select granular material: paid for by the number of cubic yards of compacted material between the payment lines as shown on the plans (Ref. K, pp. 303-306)

10. Item 5 - trench, culvert, and bridge excavation: paid for by the number of cubic yards (measured in its original position) actually excavated from within the payment lines as indicated on the plans or called for by the specifications. If not detailed on the plans, the payments limits will be considered as:

    (a) The bottom width of the trench shall be in accordance with the details shown on the appropriate standard structure sheet.

    (b) The side surfaces of the trench; these surfaces shall have an inclination of 3 vertical to 1 horizontal.

22691

Supplemental Teaching Aids:

The following are useful in providing individual help for students: Complete Secretary's Handbook 2nd ed., Doris and Miller, Parker Publishing Co., West Nyack, N.Y., 1960. Timed Writings for Typing and Transcribing, Humphrey, Lambert, and Newhouse, McGraw-Hill, New York, 1966, Word Division Manual, J. E. Silverthorn, South-Western, Cincinnati, 1958.

How To Spell It is available free from Remington Rand Corp.

Training Time 90-100 hours

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

(c) The subgrade of the roadway when under a cut section, otherwise the original surface at the site prior to the beginning of work. (Ref. K, pp. 306-307)

11. Item 18 - class 1 concrete for structures: paid for by the number of cubic yards, in the design volume, ignoring the volume occupied by the joint material, embedded metal reinforcement, structural shapes, tops of piles, or pipe with an end area of less than 1 sq. ft. (Ref. K. p. 343)

12. Item 20 - class B concrete for structures: paid for by the number of cubic yards in the design volume, ignoring the volume occupied by the joint material, embedded metal reinforcement, structural shapes, tops of piles, or pipe with an end area of less than 1 sq. ft. (Ref. K. p. 343)

13. Item 24A - bagged screened aggregate: paid for by the number of cubic yards measured in its final position within the payment lines as shown on the plans (Ref. K, pp. 353-354)

14. Item 45S - base course, bituminous macadam penetration method asphalt: paid for by the number of cubic yards of compacted material, measured in place, making no deduction for catchbasins and manholes (Ref. K, pp. 413-414)

* Note that in item 45S the bituminous material is always paid for under its respective item.

15. Item 46 - concrete foundation for pavement: paid for by the

22692

CONTENT OUTLINE

B. Items measured in cubic yards

TEACHING POINTS AND TECHNIQUES

* Emphasize that many items are measured in cubic yards, either in place or by the design volume.

* List and discuss the following as the items most commonly measured in cubic yards:

1. Item 2 - unclassified excavation

2. Item 2B - embankment in place: paid for by the number of cubic yards of material measured in its final compacted position placed within the payment limits as shown on the plans (Ref. K, p. 297)

* Note that in Item 2B the quantity of excavation is the number of cubic yards measured in its original position, excavated, and disposed of as required by the plans and specifications. (Ref. K, p. 297)

3. Item 2EC - selected borrow: paid for by the number of cubic yards measured in its original position, placed, and disposed of within the payment limits as shown on the plans (Ref. K, p. 298)

4. Item 2EC-B - selected fill: paid for by the number of cubic yards measured in place between the maximum payment lines as shown on the plans (Ref. K, p. 299)

5. Item 2EF-B - selected granular fill: paid for by the number of cubic yards measured in place between the maximum payment lines as shown on the plans (Ref. K, p. 299)

6. Item 2SP - granular fill, slope protection: paid for by the number of cubic yards measured in its final position between

22690

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	number of cubic yards by design, making no deductions for catch-basins and manholes (Ref. K, p. 418)
	16. Item 47 - cement concrete pavement: paid for by the number of cubic yards by design, making no deductions for catchbasins and manholes (Ref. K, pp. 418-419)
	17. Item 78A - stone filling: paid for by the number of cubic yards measured in its final position (Ref. K, p. 490)
	18. Item 80 - dry riprap: paid for by the number of cubic yards measured in its final position (Ref. K, p. 495)
	19. Item 80A - grouted riprap: paid for by the number of cubic yards measured in its final position (Ref. K, pp. 495-496)
	20. Item 102 - catchbasins, field inlets, manholes, and drop inlets: paid for by the number of cubic yards used or if called for in the plans by linear foot of height (Ref. K, pp. 536-538)
	21. Item 121 - topsoil placed from stockpiles: paid for by the number of cubic yards of topsoil measured in place (Ref. K, pp. 577-578)
C. Items measured in linear feet	* State that all pipes (vitrified, concrete, reinforced concrete, metal, cast iron, porous concrete, wrought iron, corrugated metal, and perforated) used for sanitary sewers, storm sewers, underdrain, water conduits, cattle passes, and culverts are always measured in the actual linear feet of the laying length installed on the project.

22693

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* List the following as items measured in linear feet: 1. Item 7 - trimming road section: measured in linear feet of road (Ref. K, pp. 316-317) 2. Item 27 - transverse joint supports: measured in linear feet of joint used (Ref. K, pp. 335-356) 3. Item 37 - metal railing: measured in linear feet horizontally between the extreme outer limits of railing furnished and placed in accordance with the plans (Ref. K, p. 403) 4. Item 94 - stone curb: measured in linear feet according to the plans (Ref. K, pp. 525-528) 5. Item 95 - stone curb granite: measured in linear feet according to the plans (Ref. K, p. 528) 6. Item 97 - concrete curb: measured in linear feet according to the plans (Ref. K, pp. 529-530) 7. Item 106A - aluminum chain link fencing: measured in linear feet according to the plans (Ref. K, pp. 542-544) 8. Item 109 - relaying pipe: measured in linear feet of laying length (Ref. K, pp. 553-554) 9. Item 113 - highway-railroad barricade: measured in linear feet, completed in place, plus an allowance of 4 linear ft. for each terminal section (Ref. K, pp. 559-560)
D. Items accounted for by units	* Point out that many items are either complete units or are applied to a

22694

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

series of small projects and are best paid for by a stated amount.

* List and briefly describe the following as items accounted for by units:

1. Item 6 - laboratory building (Ref. K, pp. 311-312)
2. Item 6B - concrete cylinder curing box (Ref. K, Addenda)
3. Item 11ES - galvanized metal end section (Ref. K, p. 329)
4. Item 11HW - galvanized metal headwall (Ref. K, p. 331)
5. Item 14ES - reinforced concrete pipe end section (Ref. K, p. 340)
6. Item 27L - longitudinal joint ties (Ref. K, p. 357)
7. Item 28B - stud shear connectors (Ref. K, p. 363)
8. Item 31 - pile shoes (Ref. K, p. 392)
9. Item 34 - guideposts (Ref. K, pp. 399-400)
10. Item 34R - resetting guideposts (Ref. K, p. 400)
11. Item 34S - removing and storing guideposts (Ref. K, p. 401)
12. Item 60D - drilling subsealing holes (Ref. K, p. 472)
13. Item 85A - splices for steel bearing piles (Ref. K, p. 512)
14. Item 88 - load tests for soils (Ref. K, p. 522)
15. Item 100 - leaching basins (Ref. K, p. 536)

22695

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	16. Item 104 - right-of-way markers (Ref. K, p. 539)
	17. Item 104X - permanent survey markers (Ref. K, p. 541)
	18. Item 106G - fence gates (Ref. K, pp. 544-545)
	19. Item 120 - reflectorized highway-railroad crossing signs (Ref. K, p. 567)
	20. Item 127 - planting (Ref. K, pp. 590-596)
	21. Item 128 - transplanting (Ref. K, p. 596)
	22. Item 129 - care of trees (Ref. K, pp. 597-598)
	23. Item 132 - tree removal (Ref. K, pp. 600-602)
	24. Items 251, 252, 253, 254 - road delineators (all types)(Ref. K, Addenda)
E. Items measured in square units	* Emphasize that the square yard, square foot, and acre are commonly used as units of measurement.
1. Square yards	* List the following as items measured in square yards and describe briefly any pertinent facts concerning them:
	1. Item 8 - preparing fine grade (Ref. K, pp. 317-318)
	2. Item 25 - metal reinforcement for concrete pavement (Ref. K, p. 354)
	3. Item 55B - surface course broken stone (Ref. K, pp. 436-437)
	4. Item 60C - color contrast for pavement (Ref. K, pp. 471-472)

22696

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	5. Item 62 - membrane waterproofing (Ref. K, pp. 474-476)
	6. Item 63 - protection course for membrane waterproofing (Ref. K, pp. 476-478)
	7. Item 79 - dry stone paving (Ref. K, p. 492)
	8. Item 79A - grouted stone paving (Ref. K, p. 493)
	9. Item 79B - dry concrete block paving (Ref. K, pp. 493-494)
	10. Item 89 - removing old bituminous carpet (Ref. K, p. 523)
	11. Item 90Y - cleaning existing pavement (Ref. K., pp. 523-524)
	12. Item 98 - concrete gutters (in square yards of exposed surface) (Ref. K, p. 534)
	13. Item 117 - surface dusting with fine aggregate (Ref. K, p. 565)
	14. Item 118 - concrete riprap in bags (Ref. K, pp. 565-566)
	15. Item 124 - sodding (Ref. K, pp. 583-586)
2. Square feet	* Describe the following as some items which are measured in square feet:
	1. Item 30B - open steel floor (Ref. K, p. 390)
	2. Item 30C - frames and grates: castings (Ref. K, pp. 390-391)
	3. Item 30F - frames and grates; fabricated (Ref. K, pp. 391-392)
	4. Item 83C - corrugated metal piling (Ref. K, pp. 499-500)

22697

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	5. Item 83S - steel sheet piling (Ref. K, pp. 499-500)
	6. Item 83T - timber sheet piling (Ref. K, pp. 499-500)
	7. Item 110 - concrete cribbing (Ref. K, p. 554)
	8. Item 110M - metal bin type retaining wall (Ref. K, pp. 555-563)
	9. Item 111 - pneumatically projected concrete (Ref. K, pp 557-559)
	10. Item 115 - bridge bearing pads (Ref. K, pp. 562-563)
3. Acres	* Give the following as examples of items which are measured in acres:
	1. Item 123 - seeding (Ref. K, pp. 579-582)
	2. Item 126 - mulching (Ref. K, pp. 589-590)
	3. Item 131 - selective thinning (Ref. K, pp. 599-600)
F. Items measured by weight	* Indicate that many measurements are made by either pounds, tons, or barrels. Mention that whenever a unit is used in the estimate, it is always used in the singular.
1. Pounds	* List the following as items which are measured in the pound unit:
	1. Item 28 - bar reinforcement for structures (Ref. K, pp. 359-361)
	2. Item 28A - spiral bar shear connectors (Ref. K, p. 362)
	3. Item 29 - structural steel (Ref. K, pp. 364-388)
	4. Item 30 - miscellaneous metals (Ref. K, p. 388)

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
2. Tons	* Mention those items which are measured in the ton unit. 1. Item 16 - furnishing and applying calcium chloride (Ref. K, p. 343) 2. Item 42 - base course: granular material (Ref. K, pp. 408-409) 3. Item 43 - base course: screened gravel (Ref. K, pp. 410-413) 4. Item 44 - base course: broken slag (Ref. K, pp. 410-413) 5. Item 45 - base course: broken stone (Ref. K, pp. 410-413) 6. Item 45SX - base course: asphalt concrete, type 1A (Ref. K, p. 415) 7. Item 51 - asphalt concrete (all types) (Ref. K, p. 421) 8. Item 122 - applying soil conditioners (Ref. K, p. 578)
3. Barrels	* Point out that cement items are always measured in barrels. A barrel of portland cement contains 376 lbs. (Ref. K, p. 342) 1. Item 15-1 - portland cement, type 1 Item 15-1A - portland cement, type 1A Item 15-2 - portland cement, type 2 Item 15-2A - portland cement, type 2A Item 15-6 - portland cement, type 6 Item 15-6A - portland cement, type 6A

22699

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	2. Item 15N - natural cement, type N (Ref. K, p. 342)
	* Emphasize that natural cement is also measured by the barrel which contains only 320 lbs.
G. Items measured in gallons	* State that oils and liquid items are measured in gallons.
	1. Item 1WA - applying water: measured in M. gal. or thousand gallon units (Ref. K, p. 296)
	2. Item 1WP - watering plants: measured in M. gal. or thousand gallon units (Ref. K, p. 296)
	3. Item 60 - treatment with bituminous material (Ref. K, p. 469)
	4. Item 61 - bituminous material (Ref. K, p. 473)
	5. Item 351 - joint sealing compound (Ref. K, Addenda)
	6. Item 352 - rubber joint material (Ref. K, Addenda)
	7. Item 361 - protective coating for concrete (Ref. K, Addenda)
	8. Item 363 - epoxy protective coating for concrete (Ref. K, Addenda)
H. Items accounted for by specific units	* Describe the following as items which are measured in specific units or in accordance with changeable field conditions.
	1. Item 82 - cofferdams: quantity is the number of square feet, found by multiplying the distance from the elevation of the base of the permanent structure to an elevation 2 ft. higher than the highest water elevation

22700

UNIT V (14.0703-12)

MACHINE TRANSCRIPTION

Performance Objectives:

Upon completion of this unit the student will be able to produce mailable copy with the second draft. She will be able to demonstrate, to the instructor's satisfaction, her planning for and preparation of a variety of materials such as manuscripts, articles, business forms, and long letters.

Unit Outline:

A. Kinds of Machines

1. Belt

2. Disc

3. Tape

B. Concepts of Effective Use of Machines

1. Corrections and special instructions

2. Use of indication slip

3. Understanding the meaning of dictation

4. Development of a pattern

5. Errors in syllabication

6. Proofreading

C. Operation

Supplemental Teaching Aids:

All of the general reference books listed for the preceding units contain material pertaining to this unit. The only book that might be added specifically for this unit is Words 5th ed., by Crank, Crank, and Connelly, McGraw-Hill, New York, 1962.

Training Time 15-20

2234

CONTENT OUTLINE

TEACHING POINTS AND TECHNIQUES

recorded at the site (while the cofferdam is being used) by the measured length of the cofferdam. (Ref. K, pp. 498-499)

2. Item 84TC - creosoted timber piles (Ref. K, pp. 503-504)

   Item 84CP - precast concrete test piles (Ref. K, pp. 504-505)

   Item 84SB - steel bearing test piles (Ref. K, pp. 504-505)

   Item 84T - untreated timber piles (Ref. K, pp. 505-510)

   Item 84TU - untreated timber test piles (Ref. K, pp. 504-515)

   Item 85C - cast-in-place concrete piles (Ref. K, pp. 512-516)

   Item 85T - tubular cast-in-place concrete piles (Ref. K, pp. 516-518)

* Note that all the items in "2" are measured by the number of linear feet of pile remaining in the finished structure.

3. Item 86C - precast concrete piles: measured by the number of linear feet of pile placed in the leads in accordance with the ordered length (Ref. K, pp. 518-521)

4. Item 107 - timber and lumber

   Item 107S - stress graded timber and lumber

   Item 108 - treated timber and lumber

* State that all the items in "4" are measured by the number of thousand

22701

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	feet (board measure) placed in the completed work. (Ref. K, pp. 550-553) 5. Item 132 - tree removal: all trees shall be measured before being cut and a unit price set for each (Ref. K, pp. 600-602) * Point out that all trees are measured 4½ ft. above the ground and referred to as diameter breast high or D.B.H.
IV. Special Items	* Explain that there are many items created for a particular situation. These items must be described and are incorporated in the Report on Design and Estimate covered in the next lesson.
A. Units of measurement	* Note that most of the special items (any arbitrary number may be assigned) are each or linear foot measurements. * Describe the following as some of the perennial items which have specific units: 1. Stone channel protection in cubic yards 2. Temporary lighting by lump sum 3. Uniformed watchman service by man days
B. Fixed lump sum items	* Describe a fixed lump sum item as a special item which is given an exact cost in the estimate and is sometimes known as a nonprofit item. * Emphasize that this item must be bid exactly as it is given in the estimate. * Explain that if a utility company desires a gas pipe on a proposed bridge, the company furnishes the pipe, sleeve, paint, and welding rod but they

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	pay for the cost of the extra steel and concrete added to support the gas pipe.
	* Note that in this small split, the cost of labor is added plus 10 percent of the total for engineering. This total figure becomes a fixed lump sum or nonprofit item.
V. The Estimate Form	* Distribute prints of a completed estimate form used on a current project.
	* Demonstrate the method of entering the necessary information on the form.
A. Prices	* Point out that prices used in any estimate reflect the prices adopted from the list published annually by the Department.
	* Explain that the prices listed are bid prices from the contracts of the year before. The cost of each item is shown for all 10 districts and then an average is taken of all the prices for that item.
	* Distribute copies of the weighted average bid prices and note that special items are not listed.
	* Mention that whenever a small quantity of any item is used, the price tends to increase.

QUESTIONS FOR REVIEW

1. Differentiate between the preliminary estimate and the engineer's estimate.
2. What is a detail sheet?
3. How does rounding the quantities in an estimate affect the general programing of highway construction?
4. Define a lump sum item.
5. Name five lump sum items.

22703

6. How does unclassified excavation differ from trench, culvert, and bridge excavation?

7. Why is concrete paid for by the amount of cubic yardage as computed by the design?

8. How is the payment computed for the installment of 300 four-foot sections of 24-in. reinforced concrete culvert pipe?

9. What is a laboratory building?

10. How is a cofferdam measured for payment?

ASSIGNMENT

1. Distribute prints of a workup detail sheet together with blank estimate forms and ask the students to complete an estimate for the project.

INSTRUCTOR'S NOTES

22704

Lesson 14 - Report on Design and Estimate

OBJECTIVES

- To complete the design of a project by consolidating the pertinent data into a final report
- To enable the student to understand the relationship of each element of design to the total project

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
I. Description	* Describe the Report on Design and Estimate as a detailed story of the complete design of a project.
	* Mention that this report is typed on 8½ by 11 in. paper, prepared for reproduction and forwarded to the Main Office for processing.
A. Purpose	* Explain that an engineer without any previous knowledge of the project may read this report and be oriented about the history and procedures of the design and all the intricacies dealing with soils, materials, other agencies, political entities, and property owners.
	* Emphasize that the report is also a control on the construction of the project since it mandates procedure, purpose, and results and is essentially the proposal for the contract. (Ref. A, p. 331)†
	* Describe the proposal as a book of instructions, procedures, and regulations for the contractor together with agreements between the contractor and the State.
B. Size	* Point out that a report can consist of a dozen pages (for a small project) but that it can become large for a major construction project.

†Reference citations shown on page 220.

22705

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Note that in this phase of the contract it is very likely that a city may request a betterment to be built under the contract which is paid for by the city. This will require a separate estimate breakdown.
	* Describe a betterment as any work done over and above a replacement of whatever existed prior to construction, e.g., furnishing and installing a 16-in. waterline where an 8-in. waterline existed.
E. Separation between construction and reconstruction	* State that a division is made between construction and reconstruction. Any of the foregoing breakdowns of estimates that apply are made for each division.
F. Federal aid contracts	* Indicate that estimates are broken down for each Federal aid project segment and for its source of funds.
	* Add that "source of funds" divides an urban section from a non-urban section and explain that an urban area is a designated area around a city and not necessarily bounded by a city line.
G. Nonparticipating shares	* Explain that some items are not paid for by the Federal Government even in a Federal aid project, e.g., resurfacing of a highway which is to be turned over to a county, town, or city.
	* State that this nonparticipating item must be in its own estimate.
H. Change in type of pavement	* Point out that a change in the type of pavement (on mainline only) requires a breakdown in the estimates.
III. Cost Analysis	* Note that next a cost analysis is made of those items which either are not listed in the published weighted average bid prices or are of such localized character that a few miles of hauling charges can drastically alter the price.

22707

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Mention that the usual items analyzed are unclassified excavation, selected granular fill, subbase course of granular material, and maintenance and protection of traffic.
A. Unclassified excavation	* Place an example of this item on the chalkboard and explain each step.

Borrow = 41% at $0.85 per C.Y.	=	$0.35 per C.Y.
Excavation = 44% at $1.00 per C.Y.	=	0.44 per C.Y.
Unsuitable material = 15% at $1.00 per C.Y.	=	0.15 per C.Y.
		$0.94 per C.Y.
Profit (20 percent)		0.19 per C.Y.
		$1.13 per C.Y.
	Say	$1.15 per C.Y.

B. Foundation course

* Add an example of Item 3R - subbase course, granular material (vibratory compaction).

Royalty	=	$0.15 per C.Y.
Loading	=	0.15 per C.Y.
Manipulation	=	0.40 per C.Y.
Haul 6 miles x 1.3 ton/C.Y. x $0.10	=	0.78 per C.Y.
		$1.48 per C.Y.
Compaction (25 percent)		0.37 per C.Y.
		$1.85 per C.Y.
Profit (20 percent)		0.37 per C.Y.
		$2.22 per C.Y.
	Say	$2.25 per C.Y.

* Indicate that many atypical highway items must be analyzed for a reasonable price. In the case of certain water pipes, the best source of information for an analysis is the local water district or companies which either furnish pipe or install pipe for the water districts.

* Note that catalogs and judgment are used as guides when determining a fair price.

IV. Field Inspections and Designers

* State that the names of all the engineers who participated in the design of the project and those who made field inspections are listed on the report.

22708

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
V. Table of Lengths	* Point out that the table of lengths must account for every foot of the new highway, whether it consists of permanent or temporary pavement. * Mention that if the project contains splits, the table of lengths is split accordingly, with a length summation for each segment.
VI. History	* State that the history of the highway is recited in the report.
A. Reconstruction project	* Note that if this is a reconstruction project, the description would cover a brief history of any previous construction.
B. Construction project	* Explain that a construction project on a new location would have no history but the justification for the project should be mentioned. * Indicate that traffic projection data is included here with estimates of generated traffic and development traffic.
VII. Type of Construction	* Stress that this portion of the report concisely explains the type of construction used for the project.
A. General description	* Discuss the descriptive matter which furnishes a brief and concise account of the overall design. 1. Pavement lanes 2. Intersections 3. Curbing 4. Ramps 5. Traffic movements 6. Railings 7. Storage lanes 8. Speed change lanes 9. Pavement types 10. Foundation courses 11. Interchanges 12. Channelizations 13. Lighting 14. Signalization

22709

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	15. Utilities 16. Landscaping
B. Grades	* Mention that the maximum and minimum grades used in the design are listed.
C. Horizontal alinement	* Note that the horizontal alinement for the entire project is briefly described. Also the maximum degrees of curvature and the types of curvature are given.
D. Foundation soils and earthwork	* Emphasize that this portion of the report gives the geological background of the area and includes: 1. Results of soil surveys 2. Description of junkyards, debris, topsoil, ballast, old building foundations, old roadbeds 3. Recommendations for handling dumping grounds 4. Locations of rock
E. Drainage	* Stress that the overall drainage system is described with emphasis on the pavement collection system, any large drainage structures, types of ditches, the use of natural waterways, and any unusual drainage situations.
F. Right-of-way	* Point out that the actual number of maps and parcels to be appropriated are divided into a rural portion and an urban portion (if necessary). * Show that all maps are grouped as to fee maps (with or without the right of access), permanent easements, temporary easements, transfers of jurisdiction, and concurrent use and jurisdiction.

UNIT VI (14.0703-03)

OFFICE EQUIPMENT

Performance Objective:

Upon completion of this unit the student will be able to score at least 90% on an instructor established scale that considers both accuracy and time in operation of adding machines and calculators. She will be able to demonstrate correct procedure and technique in operation of reproducing machines. The student will be able to tabulate 50 handwritten checks in one minute or less with no errors.

Unit Outline:

A. Machines

1. Ten-key adding machine
2. Full-key adding machine
3. Printing calculator
4. Rotary Calculator
5. Bookkeeping machine

B. Reproducing Machines

1. Spirit
2. Mimeograph-mimeoscope
3. Copy machines
4. Other reproducing machines
5. Analysis of Reproduction Requirements and Selection of Method

C. Other Office Equipment

1. Paper cutter
2. Stapler
3. Collator
4. Lablemaker
5. Punching and binding
6. Tape recorder

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
G. Bridges	* Indicate that there is a report on the bridges in the project which explains the design criteria used for loading. There is also a physical description of each bridge and the following items are covered: 1. Stationing 2. Skew 3. Use 4. Number of spans 5. Type of construction * State that a list is made of any work which must be done where the new highway passes under an existing bridge.
H. Railroads	* Explain that all at-grade crossings, spurs, relocations, and directional changes of any railroad line are described and located.
VIII. Materials and Activities	* Mention that the next portion of the report covers the procedures used during construction such as time sequences, work under certain weather conditions, and general notes concerning detours.
A. Materials	* Indicate that all materials required on the project are listed with the nearest possible sources and include: 1. Names of the sources with the haul distance to the center of the project 2. Nearest point of railroad delivery
B. Standard sheets	* Emphasize that all the standard sheets to be used on the project are listed in numerical order.
C. Maintenance and protection of traffic	* Note that in this section additional controls may be added to the basic Item 76, maintenance and protection of traffic and includes: 1. Opening to traffic certain portions of the highway before the work is accepted

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	2. Rigid control on detours and for one way traffic during construction
	3. Repair of pavement breakdowns during construction
D. Participation	* Add that the source of funds is mentioned under the remark on participation.
	* Point out that on a Federal aid project the Federal share is 50 percent and the State's share is 50 percent, while on an interstate highway, the Federal share is 90 percent.
	* Note that some contracts are paid for completely by the State.
E. General remarks	* Mention that in this portion many facts may be inserted, e.g., completion date, use of transit mix, the specifications, protection of utilities, restrictions on blasting, schedule of operations, etc.
F. Disposal of buildings	* Explain that each building is listed (if the project is split, the lists must be split) with the following information: 1. Item 120D number 2. Station 3. Offset 4. Description 5. Reputed owner
G. Special notes	* Indicate that any special notes concerning driveways, sequence of operations for utilities or for the contractor, completion time of contract, or any other extraordinary situation are inserted in simple and direct language.
H. Special bridge notes	* State that information about records and samples of subsurface explorations for bridgework are given.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	* Advise that the type of footings, abutments, and piers to be used on each bridge structure are noted.
	* Explain that the justification for bridge-foundation piles and their locations are also mentioned here.
	* Add that an explanation of how the piles will be driven is listed as well as the information of what will constitute required resistance.
	* Note that any ground water in the bridge area is located.
IX. Construction Elements	* Mention that even though the general pattern of two jobs may be similar, the two reports probably would not closely resemble each other.
A. Estimated equipment	* Indicate that a list of estimated equipment is noted and includes the absolute minimum which must be used on the project.
	* Discuss the number and types of the various pieces of construction equipment ordinarily used.
	* Read a list from a report of a current contract.
B. Encroachments	* Point out that a definite disposition of encroachments is desirable in order to avoid entanglements with the contractor at a later date.
C. Railroad cooperation	* Emphasize that if a railroad is involved, a great deal of confusion may be avoided if the relationship between the contractor and the railroad is spelled out.
	* Add that clauses involving clearances, fouling distances, scheduling, inspection of railroad work, protection of crossings, and insurance should be incorporated here.

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
D. Blasting	* State that all the rules and regulations about blasting rock are listed.
E. Cesspools and septic tanks	* Emphasize that the contractor is required to pump, treat with chlorate of lime, demolish, and backfill any existing cesspools or septic tanks within the limits of the contract. * Note that there is no direct payment for this work.
F. Stream conservation	* Indicate that stream conservation is designed to protect fish life in any stream within the contract.
X. Conclusion	* Point out that the conclusion can be the largest part of the report.
A. Special specifications	* Mention that the special specifications are actually an addenda to the specification book. Any particular effect desired may be incorporated into the ordinary item, with a complete and rational description, and the item changed in number to become a special. * Discuss the example of bar reinforcement for structures, Item 28. If more stringent regulations are to be stipulated regarding rust or if the steel must be of a superior quality from that used in Item 28, then these facts, together with specifications, are incorporated in the item and the item is changed to 28R or 28X. * Describe other special items which will be used in the contract. * Explain that there may be special items currently used but not yet listed in the book of specifications and that there may be items peculiar to the contract which may never be needed again. * Add that all items not listed in the specification book, such as water pipes for cities and villages or lighting standards of a particular type are

CONTENT OUTLINE	TEACHING POINTS AND TECHNIQUES
	listed, described, and specified in detail in this section.
B. Signalization	* Point out that on urban projects where signalization is used to a great extent, all the specifications concerning the component parts of the signal system are recorded here. * Note that this covers items such as traffic signal heads, controls, housings, deflectors, lamps, reflectors, mountings, weights, and detectors.
XI. Report Procedure	* Emphasize that despite the similarity of material, no two reports are written alike. * Mention that elaboration and order of contents is strictly an interpretation of the design engineer.

QUESTIONS FOR REVIEW

1. What is the Report on Design and Estimate?
2. Explain how a roadway cost estimate can have as many as eight splits.
3. What is meant by a "city share?"
4. Describe a table of lengths.
5. Name 10 factors of design described in the type of construction section of the report.
6. What kind of information is stated under foundation soils and earthwork?
7. What are the various types of appropriations listed separately?
8. What information is disclosed by the report on bridges?
9. What is a special specification?
10. Why is a cost analysis necessary for certain items?

ASSIGNMENT

Indicate that the first part of the next class will consist of an examination and the remaining time will be used for correcting papers.

FINAL EXAMINATION

Final Examination Part I — Matching

Instructions: Write in the space provided the number of the expression in Column B which is best suited to the expression in Column A.

	Column A	Column B
9	Critical length of grade	1. Design class 5 (rural)
17	N.C.S.	2. Safe stopping sight distance of 475 ft.
12	Estimates	3. Provides space for storage lane
19	Sign post	4. Tangent runout
6	Multileg	5. Maximum degree of curvature
10	A/L	6. Rotary intersection
14	Side friction factor	7. Refuge islands
1	Maximum grade of 5 percent	8. Diamond interchange
16	Cross-slope criteria	9. Weight-power ratio
2	60 m.p.h. design speed	10. Measurement of rate of change
13	Light intensity	11. Clearing and grubbing
11	Lump sum item	12. Splits
8	Limited R.O.W.	13. Lumen
5	Minimum safe radius	14. 0.13 at 60 m.p.h.
3	14-ft. median	15. e max.
		16. Rollover effect
		17. One-quarter inch per foot
		18. Centrifugal force
		19. Frangible base
		20. Full cloverleaf interchange

41. In the mathematical control of the centerline, the best point to equalize it to the base line would be at:

____ (a) Point of curvature

____ (b) Point on a curve

__X__ (c) Point of tangency

____ (d) Transit point

42. When lighting is designed for a ramp curve sharper than a 1500-ft. radius, the placement of luminaires on either the inside, or outside of the curve becomes a matter of judgment. If the standards were placed on the inside of the curve, the lateral spacing:

__X__ (a) Should be decreased from the tangent requirement

____ (b) Should be decreased only if the inside of the curve is on the right of the direction of travel

____ (c) Is completely independent of curvature

____ (d) Should be increased from the tangent requirement

43. The objective of the dangerous fixed object (D.F.O.) program initiated in 1967 is:

____ (a) The complete elimination of any fixed object within 30 ft. of the edge of pavement

____ (b) A positive 1 on 6 slope from the edge of shoulder to the toe or top of slope

__X__ (c) The installation of only frangible base fixed objects within 30 ft. of the edge of pavement

____ (d) The installation of a 12-ft. stabilized shoulder on a 1 on 12 slope

44. In the Report of Design and Estimate, the following item that does not require a cost analysis is:

____ (a) Selected granular fill

____ (b) Maintenance and protection of traffic

____ (c) Unclassified excavation

__X__ (d) Granite curb

22727

45. The sequence of design is done in a very definite order and consists of the following phases:

    1) Profiles

    2) Layout design

    3) Cross-section design

    4) Typical sections

    5) Centerline control

    The correct sequence of the above phases for the maximum efficiency in design is:

    ____ (a) 5, 2, 1, 4, 3

    __X__ (b) 4, 5, 1, 3, 2

    ____ (c) 5, 1, 4, 3, 2

    ____ (d) 2, 1, 3, 5, 4

46. On a high-volume highway, the effectiveness of an acceleration lane is most dependent on:

    ___ (a) The elimination of a barrier curb on the taper end of the merging lane

    __X__ (b) The available accerleration length plus the available merging length

    ___ (c) Adequate signing well in advance of the accerleration lane and on the merging lane

    ___ (d) The grade differential between the acceleration land and the through traffic lane

47. In developing a proper width for a turning roadway, the design element that would be of the least consequence is:

    ___ (a) Curvature of the highway

    __X__ (b) Superelevation of the pavement

    ___ (d) Design speed of the highway

22728

Final Examination Part II — Fill-In Statements

Instructions: Complete the following statements.

1. The principal use of the median is to prevent MEDIAL interference.

2. A bituminous pavement is referred to as a FLEXIBLE pavement.

3. The principal control for e max. is the CLIMATE.

4. In pivoting about the inside edge of a 24-ft., two-lane pavement, the theoretical gradeline is lowered __3__ in.

5. The length of the superelevation runoff is controlled by the difference between the longitudinal slope of the outside edge and the longitudinal slope of the CENTERLINE profile.

6. The tangent runout is a function of the length of spiral, the normal crown slope, and __e__.

7. In computing horizontal sight distance, the stopping sight distance is measured along the CENTERLINE of the inside lane.

8. An intersection which has more traffic lanes than the intersecting highways is defined as a FLARED intersection.

9. The trumpet interchange is known as a THREE-leg interchange.

10. The term "K" is a measure of CURVATURE.

Final Examination Part III — Multiple Choice

Instructions: Place an X in the space next to the choice which most accurately completes the statement. Read all possible answers.

1. When a 200-ft. plan and profile is furnished to all of the departments concerned, the report that would least affect the shifting or changing of the alinement is:

   ____ (a) Soils

   ____ (b) Bridge

   ____ (c) Right-of-way

   __X__ (d) Landscaping

22717

2. The time interval used in design for the total reaction time is:

____ (a) $\frac{1}{2}$ second

__X__ (b) $2\frac{1}{2}$ seconds

____ (c) 1 second

____ (d) 3 seconds

3. To fully achieve its purpose, a traffic island should have:

____ (a) Grass

____ (b) Railing

__X__ (c) Elevation above the pavement

____ (d) Lighting

4. The vertical scale used for a profile of the 50-ft. scale plan is:

____ (a) 1 in. = 5 ft.

__X__ (b) 1 in. = 10 ft.

____ (c) 1 in. = 20 ft.

____ (d) 1 in. = 50 ft.

5. The element that is not part of the geometric features of a highway is:

____ (a) Guide railing

____ (b) Signs

____ (c) Lighting

__X__ (d) Subbase

6. The selection of a design speed for a given project is based on:

____ (a) Politics

____ (b) Other highways in the area

__X__ (c) Character of the terrain

____ (d) Motor vehicle laws

22718

7. The factor which would least affect the perception time of a driver is:

____ (a) Atmospheric visibility

____ (b) Color of object

____ (c) Speed

__X__ (d) Type of vehicle

8. The coefficient of friction between the pavement and the tires of a vehicle is least affected by the:

____ (a) Pavement

____ (b) Quality of tire

__X__ (c) Contact area

____ (d) Weight of vehicle

9. The safe stopping sight distance for a 50-m.p.h. design speed is:

____ (a) 250 ft.

__X__ (b) 350 ft.

____ (c) 450 ft.

____ (d) 550 ft.

10. The lane width of a highway is directly related to the:

____ (a) Maximum curvature

__X__ (b) DHV

____ (c) Proportion of trucks

____ (d) Climate

11. The median which separates the frontage road from the main highway is known as:

____ (a) A swale median

__X__ (b) An outer separator

____ (c) An island median

____ (d) A channelized median

12. The factor that does not affect the width of a shoulder is:

____ (a) Traffic volume

____ (b) Traffic speed

____ (c) Type of terrain

__X__ (d) Type of pavement surface

13. In a typical section of a 12-ft. pavement, 12-ft. shoulder, and an 18-ft. slope at 1 on 6, the theoretical gradeline is above the top of slope:

____ (a) 48 in.

__X__ (b) 51 in.

____ (c) 54 in.

____ (d) 57 in.

14. The rate of change of grade (A/L) is most useful when determining the:

__X__ (a) Length of a truck climbing lane on a crest vertical curve

____ (b) Length of a crest vertical curve

____ (c) Drainage design of a crest vertical curve

____ (d) Sight distance on a crest vertical curve

15. The comfort effect of change in a vertical direction is greater on sag vertical curves than on crest vertical curves because:

____ (a) Vehicle impact is greater on sag vertical curves

____ (b) Vehicle impact is less on sag vertical curves

__X__ (c) Gravitational and centrifugal forces are combined

____ (d) Gravitational and centrifugal forces are opposed

16. The situation of a sharp horizontal curve at the top of a pronounced crest vertical curve can best be alleviated by:

____ (a) Leading horizontal curve with vertical curve

__X__ (b) Leading vertical curve with horizontal curve

____ (c) Starting vertical curve and horizontal curve at same point

____ (d) Compounding horizontal curve

Supplemental Teaching Aids:

The following are good resource books for this unit; Machine Office Practice, Peter L. Agnew, South-western, Cincinnati, 1965, General Office Practice, Archer, Brecker, and Frakes. McGraw-Hill, New York, 1963.

"Modern Business Machines" (20 min.), Teaching Aids Exchange, 307 South B. Street, San Mateo, California 94401 and "Maintenance of Office Machines" (36 min.) Norwood Films are applicable to this unit.

Training Time 20-30 hours

17. The use of a compound curve is justified to:

____ (a) Correct an error made in the design of the original curve

____ (b) Shorten the length of curve for economic reasons

____ (c) Eliminate a horizontal broken-back curve situation

_X_ (d) Fit the alinement to the existing terrain and topography

18. For a new highway location, drainage is most likely to be a complicated problem:

_X_ (a) Under a railroad

____ (b) On a side hill

____ (c) Over another highway

____ (d) Parallel to a river

19. To provide adequate drainage in the design of a new highway, the greatest consideration should be given to the:

____ (a) Initial cost of providing satisfactory drainage facilities

____ (b) Cost of maintaining satisfactory drainage facilities

____ (c) Distance that the collected water must be carried

_X_ (d) Satisfactory removal of precipitation from the highway

20. The following five steps are taken when planning the location of a highway:

1) Preliminary location survey

2) Traffic survey

3) Reconnaissance survey

4) Geometric design

5) Final location survey

The correct sequence of the above steps is:

_X_ (a) 3, 1, 5, 2, 4

____ (b) 2, 4, 3, 1, 5

____ (c) 2, 1, 3, 4, 5

____ (d) 1, 5, 2, 3, 4

21. An important similarity between rural highway and urban arterial highway design is the:

____ (a) Control of access is required to the same extent in both types

____ (b) Alteration and replacement of utilities is an expensive and far reaching program in both types

____ (c) Design of drainage facilities requires the same type of analysis in both types

__X__ (d) Required quality of a particular pavement surface is the same in both types

22. An analytical comparison between the new method of rounding breaking points of slopes and ditches (using a vertical curve) and the old method (using a horizontal curve) would indicate that:

____ (a) There is very little difference in the result

____ (b) The old method was more complex but gave more accurate results

__X__ (c) The new method gives more consistent results

____ (d) The new method provides for more economical maintenance

23. Since the purpose of installing guide rails is to lessen the hazard to traffic and not to protect any part of the highway structure, guide rails would most likely be used:

__X__ (a) By fixed objects close to the pavement

____ (b) On fills on steep grades

____ (c) On fills on sharp curvature

____ (d) In cuts on steep grades

24. The ratio of the centrifugal force developed when a 4000-pound vehicle rounds a 1000-ft. radius curve at 60 m.p.h. to the centrifugal force developed by the same vehicle when it rounds the same curve at 30 m.p.h. is:

____ (a) 2:1

__X__ (b) 4:1

22722

____ (c) 6:1

____ (d) 8:1

25. The classification chart recommendation that 12-ft. pavement lanes be used whenever the traffic count surpasses a design hourly volume of 70 is least concerned with the premise that:

__X__ (a) The extra cost of wider lanes is offset by the reduction in cost of maintenance due to lessened wheel concentrations at the slab edges

____ (b) The maximum allowable width of vehicles requires sufficient clearance on either side as a necessary precaution for safety

____ (c) There is an involvement with psychological factors when there is little or no lateral clearance from an obstruction adjacent to the traveled lane

____ (d) The width of any lane is a function of the traffic volume which is expected to use the highway

26. The minimun passing sight distance for a two-lane highway is determined by the sum of four distances, the longest of which is the distance:

____ (a) Traversed during perception and reaction time and during initial acceleration to point of encroachment on the left lane

__X__ (b) Traveled while the passing vehicle occupies the left lane

____ (c) Between the passing vehicle at the end of its maneuver and the opposing vehicle

____ (d) Traversed by an opposing vehicle for two-thirds of the time the passing vehicle occupies the left lane

27. The best reason for the criteria mandating a height of an object to be 4 in. for measuring stopping sight distance on crest profiles is:

__X__ (a) A lower height would drastically raise the cost of construction

____ (b) A lower height would be impractical because of the possible lack of objects lower than 4 in.

____ (c) A higher height would not substantially change the length of curve

____ (d) A higher height would exaggerate the difficulty of the night time operation

22723

28. The choice of design speed is influenced principally by the;

____ (a) Character of the terrain

____ (b) Extent of manmade features

____ (c) Economic considerations

__X__ (d) Large volume of traffic

29. The current trend of the average spot speed (the arithmetic mean of the speeds of all traffic at a specified point) is best described by:

__X__ (a) Low design speed curves yield an average spot speed close to the design speed

____ (b) High design speed curves yield an average spot speed close to the design speed

____ (c) The differential between average spot speed and design speed is independent of the alinement

____ (d) Average spot speeds have been increasing rapidly over the past 15 years

30. The criteria for establishing the length of sag vertical curve is most critical when based on:

__X__ (a) Headlight sight distance

____ (b) Rider comfort

____ (c) Drainage control

____ (d) General appearance

31. The design of a 5°-curve (R = 1146 feet) at a design speed of 60 m.p.h. indicates that the horizontal sight distance is not sufficient for the required safe stopping sight distance because the piers of a bridge obstruct the line of sight. This condition can best be corrected by:

____ (a) Moving the bridge piers farther away from the pavement

____ (b) Using a radius of 955 ft. (D = 6°)

__X__ (c) Using a radius of 1433 ft. (D = 4°)

____ (d) Lowering the sight distance requirement

22724

32. The best reason for having a controlled access highway is that:

____ (a) Animals and pedestrians are prohibited from using or crossing it

__X__ (b) Accident fatalities are reduced to one-third of those on an access highway

____ (c) The extra cost of right-of-way is not extremely expensive

____ (d) The practical capacity of the highway is guaranteed

33. The most practical approach to the selection of the proper length of spiral curve for transition between a tangent and a simple curve is based on the:

____ (a) Rate of increase of centripetal acceleration

____ (b) Gradual increase and decrease of centrifugal force

____ (c) Aesthetic effects gained by the elimination of edge profile distortion

__X__ (d) Distance needed for superelevation runoff

34. The greatest asset of a 36-ft. median cross section is that it:

____ (a) Provides a refuge for vehicles in an emergency

____ (b) Reduces the intensity of headlight glare

____ (c) Provides a storage area for plowed snow

__X__ (d) Provides freedom from medial interference

35. The most undesirable alinement condition for safety, comfort, and ease of operation would:

__X__ (a) Consist of sharp curves at the ends of very long tangents

____ (b) Consist of very long and very large radius curves

____ (c) Consist of reversals in curvature at the ends of 1500-ft. tangents

____ (d) Consist of curves at the ends of the 1500-ft. tangents

36. The most important element of a typical section is the:

____ (a) Design thickness of pavement

____ (b) Cross slope of pavement

_X_ (c) Theoretical gradeline

____ (d) Pavement surface materials

37. The determination of the right-of-way lines for a highway to be built on new location is controlled by:

____ (a) Classification chart

_X_ (b) Toes and tops of slopes

____ (c) Economics

____ (d) Design storm

38. The primary use of the curb is to:

____ (a) Control surface drainage

_X_ (b) Confine vehicles in a designated path

____ (c) Delineate the edge of pavement or median

____ (d) Assist in the development of the roadside area

39. The item not found on the standard structure sheets is:

____ (a) Delineators

____ (b) Tree planting

____ (c) Metal bin type retaining walls

_X_ (d) Concrete mixes

40. The most important factor in obtaining driver obedience of signs and traffic control devices is:

____ (a) Simplicity in design

_X_ (b) Standardization

____ (c) Police enforcement

____ (d) Strategic placement

strong, desire or attitude can be seen to have an influence on our perception.

Attitudes and adjustment determine our perception in the driving situation. Our attitudes are our personal beliefs, our way of thinking, our feelings, and our emotional reaction. Therefore, our feelings and emotions influence one's capacity for accurate and objective perception.

Anything that causes a driver to be any less efficient in the driving task, is something that should be a concern to all of us. The results of drinking and driving -- impairment of ability and traffic accidents -- are well documented.

WHAT TO DO!

There is no one answer, solution, control or countermeasure to deal with the problem of alcohol and traffic accidents. Many methods have been developed and implemented in the past decades as well as in the present. Some measures have been purely punitive in character while others have stressed the preventive aspects. However, regardless of whether they are punitive or preventive, the measures must complement each other to achieve any degree of success.

TESTING THE DRINKING DRIVER

The drinking driver is one of the major factors in the nation's traffic accident picture, and enforcement of statutory prohibitions against driving under the influence of intoxicating liquor has become a major tool in the trafficc accident enforcement program.

48. The treatment that should not be incorporated in the construction of shoulders for an urban heavy volume facility would be:

____ (a) To have jiggle bars laid transversely across the shoulder

____ (b) To use a seal coating with colored chips for contrast

__X__ (c) To use the same materials as the pavement

____ (d) To have a coarse appearance and poor riding quality

49. In the comparison between two design projects, which are similar in classification, terrain features, and right-of-way, the large difference in the cost of the projects would be reconciled because:

____ (a) The drainage work in one could be more complex than in the other

__X__ (b) One alinement could be designed on a higher gradeline than the other

____ (c) One project could have more extras than the other such as stabilized shoulders, curbs, or acceleration lanes

____ (d) One project could have larger quantities of high-cost type items than the other

50. At a public hearing for a proposed project, severe criticism of the alinement should be handled by:

____ (a) Repeating the reasons for the alinement in a very positive and authoritative manner

____ (b) Acknowledging that perhaps the alinement could have been altered but it is too late to change it

____ (c) Explaining the procedures which led to the decision of the alinement in a kind and gentle manner

__X__ (d) Informing the group that all criticisms would be recorded for further study of the alinement

UNIT VII (14.0703-04)

COMMUNICATIONS

Performance Objectives:

Upon completion of this unit the student will be able to demonstrate to the satisfaction of the instructor, a level of coherence and clarity in oral communications that is adequate for the business office. The student will be able to prepare and write a mailable letter or brief report, from facts provided by the instructor. In a role playing, or other simulated situation, the student will be able to demonstrate correct telephone technique, procedure, and usage. The student will be able to score at least 80% on an objective test covering mail handling and telegraph procedures and use.

Unit Outline:

A. Oral and Written Communications

1. Importance of oral and written communications

2. Importance of good listening

B. Elements of Good Speech

1. Voice control

2. Vocabulary and pronunciation

3. Grammar

C. Speech and Writing Problems

1. Individual analysis

2. Corrective activities

D. Review of Rules for Punctuation, Capitalization, etc.

E. Importance of the Voice in Telephone Usage

1. Control

2. Enunciation

3. Resonance

4. Tone

5. Distance between lip and mouthpiece

"TESTING THE DRINKING DRIVER"

FOREWORD

Drinking of alcohol beverages is believed to be a factor in at least half of the fatal motor-vehicle accidents, according to special studies. Routine accident reports do not show the same frequency of drinking, but there are reasons to believe such reports understate the frequency, since the necessary arrangements and equipment have not been available for alcohol tests on all of the persons involved in accidents.

The purpose of this publication is to explore the methods of controlling the driver who abuses alcohol and the components essential for setting up a control program.

INTRODUCTION

Talk about the drinking-driver problem and the methods to control it are concerned with alcohol abuse rather than its use. But to be realistic, one must know as much about its use in order to develop and evaluate programs about its abuse.

Drinking is a commonplace activity. Just as the legal, psychological, physiological, ethnic and cultural factors must be considered when analyzing the use of alcohol, these factors must be borne in mind when considering the legal, educational, rehabilitation, driving licensing, and other preventive and punitive features of a balanced program dealing with the abuse of alcohol as related to the driving task.

THE DRIVING TASK

Driving an automobile involves a series of judgment situations. The driver reacts to a stimulus in the traffic stream as he would react to a stimulus in everyday life. Therefore, the key or link between the driving situation and the ultimate driving behavior is perception. Attitudes and adjustments are factors of our perception.

Perception represents our apprehension of a present situation in terms of our past experiences. What we perceive in the traffic stream or in everyday life is dependent upon: (1) the nature of the actual stimulus; (2) the setting in which it exists; (3) our previous sensory experiences; (4) our feelings at the moment; (5) our general prejudices; (6) our desires or ambitions; (7) and out attitudes and our goals in life. Thus, any mental factor, emotional state, physical impairment,

RECOGNITION

Recognition of the drinking driver is difficult. When an officer contacts a driver he suspects of being under the influence, he must assure himself that the suspect is actually under the influence to a degree that makes him a hazard on the highway. If the officer is so assured, he must obtain evidence to be presented in court which will convince the judge and jury, as the officer himself was convinced, that the driver was in fact under the influence of intoxicating liquor.

A number of factors make this recognition difficult. First, the appearance and actions of the suspect must be different from those of a normal, sober person. When appearance and actions are clearly abnormal, it must be ascertained that alcohol is the cause. There are over 60 clinically recognized disabilities having symptons the same or similar to those of alcoholic intoxication. The officer must have reason to believe that the suspect's condition may be due to alcohol and not due to an illness, injury, or medication (drugs).

An officer or doctor, can not look at a suspect and be certain in every case that the person is or is not under the influence of alcohol. This is the reason why chemical tests to determine alcoholic influence are so important. The tests determine the presence of alcohol and make it the most probable cause of impairment of a driver. The tests also determine the concentration of alcohol in the blood and thus give an idea of the degree of impairment.

TESTING METHODS

The methods for testing the drinking driver can be classified into two general groups: observational tests and chemical tests. The first group consists of the coordination tests given drinking drivers by most police departments throughout the country. This group also includes other methods of testing for alcoholic influence, such as, movies, voice recordings, etc.

The principle of an observational test is to determine any deviation from presumed normal behavior while a person is performing a particular task. Of course, it is further necessary to determine that alcohol is the cause of any such deviation. However, the observational tests will show the state of the suspected drinking driver immediately after apprehension and are necessary to show that the person's actions indicated impairment of normal abilities.

Chemical testing is the second method used to identify the drinking driver. There are many different methods that can be used to identify alcohol in the human body. However, not all are considered adaptable for use in determining the presence and amount in drinking drivers. Chemical tests can be divided into two categories: those requiring a subsequent laboratory analysis and those permitting an immediate analysis, as in tests of exhaled breath. Laboratory analysis usually is concerned with specimens of blood and urine, although it can also include saliva.

Breath testing devices are available in two sorts, the first is for preliminary screening and the second for quantitative analysis.

The more the public is sold before the program is started, the less opposition the department will have to face later. After the program has been instituted, the selling job must still continue. This can best be done by keeping the public informed of the progress and accomplishments of the chemical test program.

ALCOHOL IN RELATION TO HIGHWAY SAFETY

Introduction

The driver who drinks is one of the major problems affecting highway safety. Yet, while most States have some laws relating to control of drivers who drive while under the influence of intoxicating liquor, most of the States need: (1) to strengthen their "drunk driving" statutes, (2) to supplement these with "implied consent" authority, and (3) to establish an expanded information collection program on the extent to which alcohol is present among drivers and adult pedestrians involved in fatal accidents.

Background

Every witness who testified before the committee expressed deep and growing concern regarding the incidence of impairment by alcohol in relation to highway accidents. Though it is, on the basis of present information, impossible to state how many accidents were in fact, or even in part, the result, of the driver's or the pedestrian's consumption of alcohol, the statistics do indicate clearly that alcohol is a factor present to some degree in about 50 percent of all accidents. This is a serious problem, and a perplexing one. Its alleviation and control will be extremely difficult, but its magnitude precludes its evasion...

Report No. 1700, House of Representatives 89th Congress, 2d Session, July 15, 1966, p. 26.

Purpose

To broaden the scope and number of activities directed toward reducing traffic accident loss experience arising in whole or part from persons driving under the influence of alcohol.

Standard

Each State, in cooperation with its political subdivisions, shall develop and implement a program to achieve a reduction in those traffic accidents arising in whole or in part from persons driving under the influence of alcohol. The program shall provide at least that:

1. There is a specification by the State of the following with respect to alcohol related offenses:

   A. Chemical test procedures for determining blood-alcohol concentrations.

of alcohol analyses with certification of individuals meeting the performance requirements established.

5. Prepare for the development of adequate means for testing for drugs other than alcohol in specimens of body materials from subject suspected of being impaired by such drugs or by other exogenous chemical agents.

Blood

The methods of analysis must meet the reliability criteria including those of accuracy, precision, and specificity acceptable to the National Highway Safety Bureau. Blood concentrations giving rise to presumptions regarding alcoholic influence shall be those obtained by analysis of specimens taken as quickly as feasible after the time of the suspected offense. When a speculative retrograde extrapolation of a blood alcohol concentration to any prior time is made, this is to be in response to a carefully designed hypothetical question, or is to be accompanied by an explanation of the presumptions necessary in making the extrapolation. It is urged that blood analyses be limited to specimens of capillary blood, that is, blood approximating arterial composition, in respect to alcohol, as soon as the requisite procedural capabilities have been attained. As blood plasma or serum are the preferred blood components for analysis, they should be designated as the preferred fluids to be analyzed in any subsequent revisions of chemical test legislation.

Breath

Breath alcohol analyses shall be performed only with apparatus, equipment, and by techniques meeting the reliability criteria including those of accuracy, precision, and specificity acceptable to the National Highway Safety Bureau. The breath methods employed in obtaining evidence for use in court shall be those utilizing breath specimens which were substantially in equilibrium with respect to alcohol with pulmonary arterial blood plasma.

The limitations in extrapolation of derived blood alcohol concentrations giving rise to presumptions regarding alcoholic influence shall be those obtaining for the direct analysis of blood. (See preceding section on blood)

Qualifications of personnel involved in the various aspects of chemical testing shall be at least those acceptable to the National Highway Safety Bureau.

Screening, or on-the-spot tests for the approximate alcohol content of breath specimens for field use by law enforcement agencies for certain limited purposes (e.g., spot checks for the purpose of detecting the incidence of impaired drivers) should employ measured specimens of breath substantially alveolar with respect to alcohol.

The results of such screening or on-the-spot tests shall not be used in any subsequent prosecution for driving or being in actual physical control of a motor vehicle while under the influence of intoxicating liquor.

Specifications and Discussion

Blood and breath are preferred over a single random urine specimen for analysis for alcohol because ordinarily it is not possible to properly conclude that the concentration of alcohol in the water of the blood at the time delivery of the urine specimen closely approaches that found in the urine itself.

Upon completion of absorption and distribution, the blood alcohol concentration decreases with time consequent to various elimination processes (oxidation, urine formulation, pulmonary vaporization, etc.) by a rate which averages about 0.018% W/V per hour, but this may vary from person to person by at least ± 50% of this figure. Blood alcohol concentration may increase with time during absorption of alcohol from the gastro-intestinal canal. In any given case the relevant information is rarely available which permits the presumption that the blood alcohol had declined with the passage of time from the arrest to the taking of the specimen. Therefore, an unbiased estimate of blood alcohol concentration at a prior time can only be made by presuming certain "facts." This should always be made clear to law enforcement officers, judges, and juries. It follows that the shorter the interval between the time of arrest and specimen collection the better. It is believed this interval need not exceed one hour in the case of most arrests. To define statutorily the offense as that of having a blood alcohol concentration in excess of a given figure at the time of taking of the specimen appears to be the preferred means of eliminating this vexing aspect of chemical testing.

The use of capillary blood for alcohol analysis is preferred because this blood has a composition approaching that of arterial blood in respect to alcohol and if the plasma or serum of such blood is analyzed, the result obtained is directly comparable to the result obtained by calculation from a simultaneous breath analysis.

In the analysis of blood specimens at least duplicate determinations should be performed on each specimen. If the results agree within ± 10% of the mean, the mean should be reported as the result. If the agreement is not within these limits, each result obtained should be reported. Blood alcohol results should be expressed in terms of %W/V, i.e., grams of

The preliminary screening devices are portable items for testing breath and maybe used to confirm a police officer's suspicion that alcohol may be present. The officer is then able to subject the suspect to further testing in order to determine the precise amount of alcohol present, whether by laboratory analysis or with another breath device giving quantitative results.

It is an accepted fact that the amount of alcohol in the breath is a reliable index of the concentration of alcohol in the blood, which in turn is an accurate index of the amount of alcohol reaching the brain and affecting the judgment and abilities of the individual. Established methods of determining breath alcohol, when properly conducted, provide reliable and accurate information regarding the presence and concentration of alcohol in the blood.

An enforcement agency's choice of which test method to employ will be dictated by what facilities are available in its area. If the police department has a good laboratory, it may easily conduct blood or urine tests itself. If competent personnel are available, a breath testing program may be used. If hospital, clinic, or health department laboratories can assist, the agency may make use of these facilities to help gather the information necessary for adequate prosecution of drinking drivers.

A chemical test by itself is usually not sufficient to bring about conviction of persons charged with driving while under the influence. Evidence needs to be presented that the suspect's physical abilities

were impaired, in addition to the fact that the reason for impairment was the presence of alcohol in the blood. For this reason, both observational tests and chemical tests are essential for a good enforcement program dealing with drinking drivers.

BLOOD ALCOHOL STANDARDS

The National Highway Safety Bureau's Highway Safety Program Standard 4.4.8 Alcohol in Relation to Highway Safety (Appendix A) specifies that each state in cooperation with its political subdivisions, shall have a program at least that:

> "I. There is specification by the State of the following with respect to alcohol related offenses:
>
> A. Chemical test procedures for determining blood alcohol concentrations.
>
> B. (1) The blood alcohol concentrations, not higher than 0.10 per cent by weight, which define the terms "intoxicated" or under the influence; and
>
> (2) A provision making either unlawful, or presumptive evidence of illegality, if the blood-alcohol concentration of a driver equals or exceeds the limit so established."

Article 11-902.1 of the Uniform Vehicle Code contains the presumptions defining under the influence of intoxicating liquor:

> "I. If there was at that time 0.05 percent or less by weight of alcohol in the person's blood, it shall be presumed that the person was not under the influence of intoxicating liquor.
>
> 2. If there was at that time in excess of 0.05 percent but less than 0.10 percent by weight of alcohol in the person's blood, such fact shall not give rise to any presumption that the person was or was not under the influence of in-

2238

toxicating liquor, but such fact may be considered with other competent evidence in determining whether the person was under the influence of intoxicating liquor.

3. If there was at that time 0.10 percent or more by weight of alcohol in the person's blood, it shall be presumed that the person was under the influence of intoxicating liquor.

4. Percent by weight of alcohol in the blood shall be based upon grams of alcohol per 100 cubic centimeters of blood. (REVISED, 1968.)"

Many states have enacted legislation that contain the above standards on alcoholic influence. (Apendix B)

TESTING PROCEDURE

Many police agencies have regulations for handling of the drinking driver. The following paragraphs are intended to explain what elements are necessary to carry out a successful program and aid in the prosecution of drivers found under the influence.

For a driver to be charged with driving while under the influence of alcohol, it must be established that he was, in fact, driving a vehicle or in physical control of it at the time he was apprehended. To complete the charge, it must be ascertained that the suspect was under the influence of alcohol to such a degree that his driving abilities were impaired. All deviations from normal driving behavior (including extreme caution) and all violations should be noted.

If an arresting officer suspects a person of being under the influence, he should take the suspect to the police station or jail for a more complete examination, where other witnesses are present and

there are better facilities available for observation and the performance of a chemical test.

Satisfactory examination of a suspect is made easier through the use of the Alcoholic Influence Report Form. (Appendix C) The form is designed to give an officer a uniform guide in observing, testing, and interviewing a suspect. It is intended to record impairment in coordination and judgment, and to assist an officer to arrive at a conclusion that the individual is normal or his driving abilities are impaired.

SETTING UP CHEMICAL TESTS FOR ALCOHOLIC INFLUENCE

A program of chemical testing for alcoholic influence can be most helpful in dealing with the problem of the drinking driver. The program must, however, be properly planned and carried out if it is to be effective. Chemical tests are not a cure-all for the problem of the drinking driver, but they are an example of the application of scientific methodology police work aimed at in providing the court with positive, reliable evidence with which to judge the violator and in obtaining information regarding the relationship of alcoholic impairment to traffic accidents.

The police are the most intimately concerned with the program. They in general and the top command in particular, must be well aware of the benefits and pitfalls of such a program. While chemical tests definitely identify alcohol in the system of the suspect, the individual police officer is not relieved of the other necessary work in connection with a driving while under the influence (DWI) case. On the

contrary, additional effort by the officer is necessary and care must be taken in observing and recording the suspect's outward systems of alcohol influence.

Chemical tests of body fluids and breath determine the presence and concentration of alcohol in the blood of persons who have been drinking alcoholic beverages. Tests of blood, breath or urine are being used by over 1,000 communities in prosecuting persons charged with driving while under the influence.

The various established methods of analysis are scientifically sound and, when properly conducted, provide accurate information. There is adequate legal precedent to allow the introduction of this evidence. A number of states have laws which not only provide for the admissibility of the scientific findings, but also establish presumptions that give concentrations of blood alcohol are evidence of alcohol influence or sobriety, insofar as the operation of a motor vehicle is concerned. In addition, as of March 1, 1970, 46 states have implied consent laws whereby any person placed under arrest for operating a motor vehicle while intoxicated or under the influence of alcohol is deemed to have given his consent to a chemical test for the purpose of determining alcoholic content. If the person does not live up to this implied agreement he forfeits the privilege to use the highways in that state. See Appendix B for the list of States with various drinking-driver legislative provisions.

THE ESSENTIAL ELEMENTS

The initiation of a program of chemical testing for alcoholic in-

22745

fluence is a task to approach with much caution. Many factors must be considered to assure the success of the program. A community does not just start doing it; comprehensive plans must be made:

1. Official approval must be obtained
2. Facilities provided
3. Materials purchased
4. Training must be completed
5. Public acceptance and approval must be developed

As stated earlier, a good program of chemical testing is an indication of conscientious and progressive police work, and it requires a determined effort on the part of all concerned to be effective.

The various phases that must be considered for an effective program are outlined in Appendix D and Appendix E.

Appendix D is "A Model Program For The Control Of Alcohol For Traffic Safety" developed by the National Safety Council's Committee on Alcohol and Drugs for the National Highway Safety Bureau of the United States Department of Transportation. It deals with all program considerations, including chemical tests, putting each phase into proper perspective.

The "RECOMMENDATIONS OF THE AD HOC COMMITTEE ON TESTING AND TRAINING" of the Committee on Alcohol and Drugs, National Safety Council, are contained in Appendix E. Here the minimum standards of training for interpretation, scientific direction, technical supervision, sample analysis and remote sampling are specified.

TEST METHOD

One of the major factors to consider in setting up a program of chemical tests for alcoholic influence is the selection of the method to be employed. The reliability of the several methods of determining the presence and concentration of alcohol in specimens of body origin are well established.

Each community must evaluate its capacities and needs to determine which test method will be best suited for use. Listed below are some of the major factors to consider in choosing a test method.

Cost -- A breath test method involves an immediate cost of the apparatus to be used, while other methods make use of the existing facilities of hospitals, health departments, and private clinics. If the work involved in any method is done with a police department as part of the regular duties, the cost per test will be quite low. If these services are performed by outside personnel, the cost is increased.

Facilities -- The availability of a police laboratory or that of a hospital, clinic, or health department will determine the choice of a blood test method. If none of these facilities are available especially during the hours of darkness, a community would probably be inclined to choose a breath method.

Time -- Another factor to be considered is the time element, that is, the time required for each test. Blood tests usually take longer than breath tests. Time is also a factor in regard to how close the test facility is located. If too far away, the portability of a breath test device may be a determining factor.

Number of Tests -- Small municipalities might have a small number of tests to run each year which would not justify a

22747

large outlay of capital for equipment and training. In some areas a cooperative arrangement is made whereby different police agencies make use of the same facilities.

Personnel -- The availability of qualified personnel is perhaps the most important of the factors. Within this factor also lies the training of all personnel from police officer to prosecutor and scientific expert, all of whom will be concerned with chemical tests. The success of the program will depend upon the competence and abilities of the personnel involved -- chemists must be exact in their analyses; police officers thorough in their reporting; technicians well-practiced with breath devices; medical experts qualified by experience; and prosecutors attentive to each detail of the case. With personnel of this sort and a receptive court, the program can be successful.

Statutory Provisions -- The statutory provisions of the state must be reviewed to see what is and is not provided, to include authority, limitations, choices afforded subjects, immunity, etc.

As can be seen from the foregoing paragraphs, many factors are involved in the determination of the method to be used. These factors will vary in importance dependent upon local circumstance. Regardless of what type test method is finally decided upon, due consideration must be given each and every one of the factors mentioned so that unforeseen obstacles will not arise later.

When a decision has been reached on the procedure to be used, be it blood or breath, or a combination of methods, then the job of selling the program must be accomplished before it is actually put into operation.

B. (1) The blood-alcohol concentrations, not higher than .10 percent by weight, which define the terms "intoxicated" or "under the influence of alcohol," and

(2) A provision making it either unlawful, or presumptive evidence of illegality, if the blood-alcohol concentration of a driver equals or exceeds the limit so established.

II. Any person placed under arrest for operating a motor vehicle while intoxicated or under the influence of alcohol is deemed to have given his consent to a chemical test of his blood, breath, or urine for the purpose of determining the alcohol content of his blood.

III. To the extent practicable, there are quantitative tests for alcohol:

A. On the bodies of all drivers and adult pedestrians who die within four hours of a traffic accident.

B. On all surviving drivers in accidents fatal to others.

IV. There are appropriate procedures established by the State for specifying:

A. The qualifications of personnel who administer chemical tests used to determine blood, breath, and other body alcohol concentrations.

B. The methods and related details of specimen selection, collection, handling, and analysis.

C. The reporting and tabulation of the results.

V. The program shall be periodically evaluated by the State, and the National Highway Safety Bureau shall be provided with an evaluation summary.

APPENDIX B

Drinking and Driving Laws

April, 1970

State	Year "Chemical Test" Law Enacted	Presumptive Level	Year "Implied Consent" Law Enacted
Alabama	1969	0.10%	1969
Alaska	1969	0.10%	1969

UNIT VIII (14.0703-10)

TRANSPORTATION

Performance Objectives:

Upon completion of this unit the student will be able to score at least 80% on an instructor made objective test dealing with types of transportation available and services of travel agencies.

Unit Outline:

A. Types of Service

1. Identification of methods of travel

2. Variations in uses, costs and processes

B. Sources of Travel Assistance

1. Agencies

2. Air line ticket offices

C. Hotel and Motel Reservations

D. Duties During Employer's Absence

Supplemental Teaching Aids:

A possible source of resource people or material is the local Hotel/Motel Managers Association. Periodicals applicable to this unit are the following: Hotel Red Book, American Hotel Directory Association, New York, Official Airline Guide, American Aviation Publications, Washington, D. C., TDIC (Transportation Displays, Inc.,) 70 East 45th St., New York.

Training Time 2-4 hours

State	Year "Chemical Test" Law Enacted	Presumptive Level	Year "Implied Consent" Law Enacted
Nevada	1958	0.15%	1969
New Hampshire	1949	0.15%	1965
New Jersey	1950	0.15% *(ID)*	1966

APPENDIX D

A MODEL PROGRAM FOR THE CONTROL OF ALCOHOL FOR TRAFFIC SAFETY

developed by the
National Safety Council
Committee on Alcohol and Drugs
for the
National Highway Safety Bureau
United States Department of Transportation

July, 1967

A MODEL PROGRAM FOR THE

CONTROL OF ALCOHOL FOR TRAFFIC SAFETY

Each state must have a program designed to minimize the contribution of alcohol as a causative factor in traffic accidents. The program shall include educational and legal elements and a means for continued program evaluation. It shall be a balanced program emphasizing both preventive and punitive features of control of alcohol for traffic safety. All elements of the program shall maintain effective liaison in respect to their activities and policies.

I. PUBLIC INFORMATION AND EDUCATION

A. Public Information

Each state shall develop and activate a plan for effective communication with relevant segments of the public in respect to:

1. The nature and extent of alcohol involvement in traffic accidents.

2. Means to prevent and to control this involvement.

Pertinent information shall be directed towards selected target groups in addition to the public at large. These include the categories of users of alcohol, abstainers, the medical and legal professions, law enforcement agencies, various driver organizations, and educational institutions. The goal of this activity will be the accomplishment of an attitude-change toward drinking and driving.

B. Education

Each state shall provide, through its system of education, teaching materials relevant to alcohol and traffic safety to educational institutions, especially secondary schools. It will also conduct through appropriate educational channels training conferences for vocational and professional groups with direct program responsibility such as driver training instructors, and the police, prosecutors, and judges. Educational programs in the attack upon traffic-alcohol death and injury should be developed with liaison and in cooperation with groups in national, state and local government, and also with any other groups which are responsible for and experienced and concerned with (a) education, (b) other alcohol problems, and (c) other traffic problems.

II. LEGAL

A. Legislative

Each state should enact legislation which includes the following items:

1. That it is an offense to drive or operate or to be in actual physical control of any vehicle while under the influence of alcohol.

2. A chemical test law establishing admissibility of chemical test evidence in criminal and civil cases and establishing presumptive levels in respect to alcohol influence.

3. An implied consent law by which a driver on the highway is deemed to have given his consent to a chemical test, or alternatively, legislation making chemical tests compulsory for persons involved in accidents while driving or operating a vehicle. (See section on Law Enforcement)

4. Provisions for central state control of chemical test methods and certification of qualified persons to conduct chemical tests.

5. Authorization of law enforcement officers to apprehend drivers under the influence of alcohol without warrant in the same manner as in felony cases--upon probable cause.

6. Regulation of post mortem investigation with at least the following features:

   (a) Compulsory requirement for coroners and medical examiners to perform post mortem investigations of all vehicular-related deaths occurring within six hours as a result of accident or other happening.

   (b) That no person (funeral director, embalmer, etc.) having custody of the body of such a deceased person shall perform any internal embalming procedure until authorized to do so by the physician who has performed or shall perform the post mortem examination.

7. Mandatory revocation of the operator's license upon conviction for driving while under the influence of alcohol.

22758

8. Authorization of discretionary administrative action in suspending the operator's license when there is sufficient evidence that the licensee has committed an offense for which mandatory revocation of license is required upon conviction.

9. Establishment of immunity from lawsuits for physicians and other qualified persons withdrawing blood specimens from arrested motorists at the request of law enforcement officers.

10. The requirement that analysis for alcohol of the specimens obtained in such deaths shall be conducted by a procedure which is considered specific for ethyl alcohol and which will therefore distinguish among ethyl alcohol, isopropyl alcohol, methyl alcohol, formaldehyde, and acetone.

Specifications and Discussion

The Uniform Vehicle Code (Revised--1962) should be used as a guide in formulating legislation in respect to most of the various items: Item 1, Section 11-902 (a); Item 2, Section 11-902 (b); Item 3, Sections 1-155, 6-205.1, 6-208, 6-211, 11-902; Item 4, Section 11-902 (c); Item 5, Section 16-105 (a); Item 7, 6-205; Item 8, 6-206.

A procedure specific for alcohol should be used in death investigations for the sake of specificity itself, and to avoid measuring the varying and possibly quite large quantities of nonalcohol volatile reducing substances in specimens exhibiting putrefaction. In addition, an appropriate procedure shall be one which detects the components of embalming fluids when present.

B. Law Enforcement

All police agencies must adopt and maintain programs for prevention, detection, apprehension, and the processing of motor vehicles offenses by those persons whose driving ability is impaired by alcohol as defined by existing statute. Preventive procedures shall include cooperation and participation in educational matters (see section on Public Information), and careful administrative assignment and allocation of manpower for deterent purposes, including surveillance of drivers whose licenses have been suspended. In addition spot check tests, or tests with blockades should be encouraged as deterrents. Continued efforts to strengthen the relationship between police agencies, prosecutors, courts and the public are to be encouraged.

Measures for detection, apprehension, and processing of suspects shall include an appropriate amount of instruction of officers regarding:

1. The various manifestations of alcohol impairment, especially in connection with motor vehicle operation.

2. Proper acquisition and recording of the information requested in the Standard Accident Report Form.

3. Employment of chemical test devices.

4. The proper execution of the Alcoholic Influence Report Form including the performance and evaluation of appropriate behavioral tests.

5. The possible recognition and procedures for investigation of individuals under the influence of drugs other than alcohol, and referral to appropriate agencies of individuals with natural illness and injuries.

C. Chemical Tests

In each state an appropriate designated agency shall:

1. Promulgate regulations concerning the collection, preservation, and storage of blood, breath, and other body substances and for analysis of these for alcohol content. Analyses shall be performed only on specimens of blood, breath, or urine in the case of living subjects. Blood and breath are to be preferred. Choice of specimens from subjects of autopsies is at the discretion of the physician. Specimens of blood from sites not likely to be affected by admixture or diffusion of alcohol from the gastrointestinal tract contents are to be preferred.

2. Develop a suitable program for periodic monitoring of performance ("quality control") of laboratories performing blood or urine alcohol analyses and agencies or laboratories involved in the use of breath alcohol devices.

3. Provide information and advice relevant to chemical testing to law enforcement agencies and other interested parties.

4. Provide for appropriate training in the performance

alcohol per 100 milliliters of blood to the second decimal place. The test result reported in the case of breath analysis should be the mean of the results of the analysis of at least two separately collected breath specimens providing the results agree within ± 10% of the mean value. If the results do not agree within these limits, all results obtained should be reported. Breath alcohol analyses should be expressed in terms of the corresponding blood alcohol concentrations as directed in the case of direct analysis of the blood. As revisions in chemical test legislation are enacted it is recommended that the alcohol concentration in liquid specimens be expressed as mgs of alcohol per 100 ml of fluid with the third figure being zero in each case (e.g., 166 mgs per 100 ml found would be reported as 160 mgs per 100 ml of, etc.).

It is hoped that in the future breath quantities of alcohol may be defined in terms of milligrams of alcohol per unit volume of breath which is substantially alveolar in composition with respect to alcohol, thus avoiding the necessity of making any indirect calculation to a presumed blood alcohol concentration equivalent.

One or more laboratories in each state should prepare for the development of means for testing for drugs other than alcohol in subjects suspected of being impaired by the affects of such drugs or other exogenous chemical agents. It is recommended that the National Highway Safety Bureau accumulate information on such matters as (1) the effects of individual drug substances on human performance relevant to driving, and (2) choice and quantities of specimens for individual drug determinations, individual procedures for such determinations, and screening procedures for drug substances, especially the narcotic analgesics, sedatives, antihistamines, tranquilizers, psychodelics, other psychopharmacologic agents, and other central nervous system affectants which might be encountered in drivers. It is urged that the National Highway Safety Bureau arrange for the communication of the information (or listings of its sources) to an appropriate state official who in turn should transmit this to the various individual laboratories for immediate implementation to the degree each state deems fit. It is also recommended that existing information on the incidence and significance of drugs other than alcohol in drivers be accumulated and that further investigation of the incidence and significance to be encouraged. When and if, in the view of the National Highway Safety Bureau, sufficient justifying information has been accumulated, the Bureau should establish minimum criteria for testing for such drugs analogous to criteria for testing for alcohol.

Personnel qualifications for the education, training and experience of all individuals concerned with the technical aspects of chemical testing shall be at least those acceptable to the National Highway Safety Bureau. The details of individual program supervision by the state agency ought at least to meet the minimum requirements of the National Highway Safety Bureau.

22763

D. Behavioral Tests

Behavioral tests and observation for possible impairment should be made on every driver involved in accidents investigated by the police, and on every driver who is arrested on suspicion of driving while under the influence of alcohol. The Alcoholic Influence Report Form developed by the National Safety Council Committee on Alcohol and Drugs should be the minimum guide used in examining, interpreting, and recording the results of such tests and the form should be expanded to contain instructions to better standardize its use. The use of photographs, motion pictures, video tapes, and sound recordings to document behavior should be encouraged.

E. Prosecution

Each state shall conduct regular periodic court conferences within the state, making it mandatory for all judges and prosecutors in those courts having jurisdiction of offenses involving driving while under the influence of alcohol to attend. In such conferences all problems concerning prosecution and rehabilitation of the drinking driver and their solutions may be considered. These conferences should be integrated, when feasible, with the other elements of the educational program. To eliminate the unwarranted reduction of charges against motorists arrested for driving or being in actual physical control of a vehicle while under the influence of alcohol the administrative suspension of the operator's license described in legislative section (see above) is recommended.

III. PROGRAM EVALUATION

Each state shall devise a system of periodic program evaluation adequate to determine the effectiveness of each element of the program. Such a system must include arrangements for external as well as internal inspection; for example by the National Highway Safety Bureau. Results of the program evaluation are to be made available to the governor of the state and the National Highway Safety Bureau at one-year intervals. This report may be made a part of a more comprehensive report dealing with other aspects of the total Highway Safety Program.

UNIT IX (14.0703-08)

FINANCIAL ACTIVITIES

Performance Objectives:

Upon completion of this unit the student will be able to score at least 80% on an instructor developed objective test covering the handling and verifying of forms involved in ordering, receiving, selling, and general financial records. Also covered in this test should be common reports required by governmental agencies.

Unit Outline:

A. Importance of the Need of Financial Records

B. Types of Records

1. Personnel
2. Payroll
3. Sales and purchases
4. Inventory
5. Taxes
6. Financial statements
7. Petty cash
8. Budgets
9. Credit applications

Supplemental Teaching Aids:

An excellent resource person for this unit is a staff member from the college business office. Free or inexpensive information is available from the Massachusetts Bankers Association, 125 High St., Boston, 12110. Of some value is the comic book- The Story of Checks, available from the Federal Reserve Bank of New York.

Training Time 8-10 hours

APPENDIX E

E-1

RECOMMENDATIONS OF THE AD HOC COMMITTEE ON TESTING AND TRAINING OF THE COMMITTEE ON ALCOHOL AND DRUGS NATIONAL SAFETY COUNCIL

April 29 and 30

1968

Florissant, Colorado

PREAMBLE

For the purposes of traffic law enforcement and in connection with programs for the control of alcohol in respect to traffic safety, this Ad Hoc Committee concurs unanimously in making the following recommendations in the light of currently available information.

I. SPECIMENS

A. The biological specimens of choice for the determination of ethyl alcohol are those of blood or breath.

B. Suitable breath specimens are those in which the ethyl alcohol was substantially in equilibrium with the alcohol of the pulmonary arterial blood plasma.* "Deep lung air" (alveolar air) is such a specimen.

C. Urine. Because of various problems in the interpretation of the results of analyses of urine specimens for alcohol which cannot readily be overcome in law enforcement practice, analysis of urine for the purpose of determining blood alcohol concentration is to be discouraged except under the strictly controlled conditions employed in determining renal solute clearances.**

II. PROCEDURES FOR ANALYSIS

A. Procedural controls

1. Analytical procedures for breath alcohol analysis should include the following controls in conjunction with the testing of each subject:

a) Continuous observation of the subject for at least fifteen (15) minutes prior to collection of the breath specimen, during which period the subject must not have ingested alcoholic beverages or other fluids, regurgitated, vomited, eaten or smoked.

b) A blank analysis.

c) Analysis of a suitable reference or control sample, such as air equilibrated with a reference solution of known alcohol content at a known temperature, the result of which analysis must agree with the reference sample value within the limits of $\pm$ 0.01% W/V. This analysis shall immediately precede or immediately follow the analysis of the breath of the subject.

---

* See E-7 to E-11 for pertinent references

RECOMMENDATIONS OF THE AD HOC COMMITTEE

2. Analytical procedures for blood alcohol analysis should include the following controls in conjunction with any sample or series of samples analyzed sequentially or simultaneously:

   a) A blank analysis where appropriate.

   b) Analysis of a suitable reference or control blood sample of known alcohol content within the range of 0.10 to 0.30% W/V, the result of which analysis must agree with the reference sample value within the limits of ± 0.01% W/V.

B. Reporting of Results

1. Results of alcohol determinations expressed as blood alcohol concentrations be reported to the second decimal place if expressed in terms of W/V or W/W, or to the same degree of precision if reported in other units of concentration such as milligrams per 100 milliliters.

C. Quantification of Breath Specimens

1. The quantity of breath analyzed for its alcohol content shall be established only by direct volumetric measurement, or by collection and analysis of a fixed breath volume.

III. STANDARDS OF TRAINING

In order to implement and monitor the application of the above and other applicable standards, the Ad Hoc Committee unanimously recommends the following minimum standards of training. For the purposes of the section, the activities of a program of chemical testing for alcohol will be classified as follows:

Interpretation
Scientific Direction
Technical Supervision
Sample Analysis
Remote Sampling

Although the titles assigned to the individuals associated with these several activities may vary in different jurisdictions, their functions generally will be expected to remain the same.

These recommendations are intended to describe the minimum training and educational requirements deemed necessary to ensure

efficient and dependable administration of a program of chemical testing for alcohol. They are not intended to provide guidelines for all aspects of a chemical test program.

A. Interpretation

In any chemical testing program there should be readily available professional personnel to provide expert testimony and to interpret the pharmacological and physiological significances of the analytical results.

No specific training recommendations are made at this level of professional competence in the light of the adequacy of the basis academic and professional education of such individuals.

B. Scientific Direction

A program of chemical testing for alcohol must be under the supervision of a scientific director. The director should have at least a baccalaureate degree in one of the natural sciencies or other appropriate field, and, in addition, specialized knowledge may be obtained through attendance at a course of instruction specifically designed for this purpose, or by nine months residency training in a recognized laboratory carrying out such functions.

If the program includes the direction of a laboratory that carries out direct analyses of blood samples for alcohol, the Director and the analysts under his supervision should possess at least the educational and experience qualifications set forth for these personnel categories in Title 20, Code of Federal Regulations, Chapter III, Part 405, Paragraphs 405.1312, 405.1313, 405.1315*, or equivalent educational and experience qualifications in other appropriate disciplines such as chemistry, criminalistics, or toxicology or combination thereof.

C. Technical Supervision

Technical supervision of chemical tests for alcohol must be exercised continually. The responsibilities of the technical supervisor include field inspection, maintenance and calibration of breath testing equipment, and training and re-evaluation of the breath test technicians under his jurisdiction. Further, he is responsible for periodic re-examination of the operators under his jurisdiction to ensure technical knowledge and competence.

---

* Federal Health Insurance for the Aged ("Medicare") Regulations: Conditions for Coverage of Services of Independent Laboratories, February, 1968. See extracts from these regulations in E-15 to E-24.

For individuals exercising the preceding functions, the minimum qualifications are:

1. High school graduation or its equivalent.

2. Accreditation as an operator of the chemical test method he is to supervise, or possession of equivalent knowledge to qualify him as such.

3. Satisfactory completion of a technical supervisors' course, the content of which should include:

   a) Advanced survey of current information on the physiology and pharmacology of alcohol.

   b) Operational principles and theories applicable to the program.

   c) Instrument maintenance and calibration.

   d) Legal aspects of alcohol and traffic.

   e) Public relations aspects of alcohol and traffic.

   f) Principles of instruction.

D. Breath Testing Technicians

In lieu of formal educational requirements, a pre-course screening test may be used to determine the technical aptitude of prospective technicians. The recommended course of instruction includes the following subject matter: (The term "hour" as used in these recommendations refers to a 60-minute period of instructional time).

1. A minimum of three (3) hours of instruction on alcohol and the human body.

2. A minimum of three (3) hours of instruction on the operational principles of the selected testing method which is to include:

   a) A functional description of the testing method.

   b) A detailed operational description of the method with demonstrations.

3. A minimum of five (5) hours of instruction on the legal aspects of chemical tests generally and of the particular method to be employed.

4. A minimum of three (3) hours of instruction on supplemental information which is to include nomenclature appropriate to the field of chemical tests for alcohol.

5. A minimum of ten (10) hours of laboratory participation using appropriate equipment. Laboratory practice will include the use of reference alcohol samples, as well as the testing of actual drinking subjects.

6. A minimum of one hour of formal examination for purposes of determining the competency and qualifications of the technician or trainee.

E. Remote Collection of Specimens

This instruction should be provided within the context of local law enforcement training in the subject area of traffic law enforcement procedures. Additional instruction should be given where applicable in the remote collection of blood or breath specimens for subsequent analysis.

1. Blood Collection - In lieu of extensive training in this specific area, a standard collection kit should be utilized. It should include detailed instructions for the medical personnel responsible for the withdrawal of the blood specimen and emphasize pitfalls to be avoided. Law enforcement officers are laso to be acquainted with the proper employment of this kit in the collection and submission of the blood specimens for subsequent analysis.

2. Breath Collection - Law enforcement officers who are to collect breath specimens should be acquainted with those technical and environmental factors that might affect the validity of the subsequent analysis. They should receive instruction in the principles and use of any collecting device employed sufficient to become proficient in its use; should be acquainted with the scientific significance of the test to be conducted and should be acquainted with the proper techniques for the submission of collected specimens for analyses.

This Ad Hoc Committee estimates training for this activity will require a minimum of three (3) hours of instruction.

Continued training should be provided to communicate new developments apropos of the selected testing method and other aspects of chemical testing for alcohol.

HEALTH INSURANCE

FOR THE AGED

(CODE OF FEDERAL REGULATIONS,
TITLE 20, CHAPTER III, PART 405)

REGULATIONS

U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE
SOCIAL SECURITY ADMINISTRATION

405.1312 Condition - Clinical Laboratory; Laboratory Director. - The clinical laboratory is under the direction of a qualified person.

(b) **Standard Laboratory director - qualification.** The laboratory director meets the requirements of subparagraphs (1), (2), (3), or (4), and (5) of this paragraph:

(1) He is a physician certified in anatomical and/or clinical pathology by the American Road of Pathology or the American Osteopathic Board of Pathology or possesses qualifications which are equivalent to those required for such certification (board eligible).

(2) He is a physician who (i) is certified by the American Board of Pathology or the American Osteopathic Board of Pathology in at least one of the laboratory specialties, or (ii) is certified by the American Board of Microbiology, the American Board of Clinical Chemistry, or other national accrediting board acceptable to the Secretary in one of the laboratory specialties, or (iii) subsequent to graduation has had 4 or more years of general laboratory training and experience of which at least two were spent acquiring proficiency in one of the laboratory specialties in a clinical laboratory - with a director at the doctoral level - of a hospital, a health department, university, or medical research institution, or in a State which regulates clinical laboratory personnel, in a clinical laboratory acceptable to that State.

(3) He holds an earned doctoral degree from an accredited institution with a chemical, physical, or biological science as his major subject ("accredited," as used herein, refers to accreditation by a nationally recognized accrediting agency or association, as determined by the U.S. Commissioner of Education) and (i) is certified by the American Board of Microbiology, the American Board of Clinical Chemistry, or other national accrediting board acceptable to the Secretary in one of the laboratory specialties, or (ii) subsequent to graduation, has had 4 or more years of general clinical laboratory training and experience, of which at least 2 years were spent acquiring proficiency in one of the laboratory specialties in a clinical laboratory - with a director at the doctoral level - of a hospital, a health department, university, or medical research institution, or in a State which regulates clinical laboratory personnel, in a clinical laboratory acceptable to that State.

(4) For a period ending June 30, 1971, an exception to the requirements in subparagraph (1), (2), or (3) of this paragraph may be made if the conditions described in (i) and (ii) below are met:

(i) the director was responsible for the direction of a clinical laboratory for 12 months within the 5 years preceding July 1, 1966, and, in addition, meets one of the following requirements:

(a) The director holds a master's degree from an accredited institution with a chemical, physical, or biological science as his major subject and subsequent to graduation has had at least 4 years of pertinent clinical laboratory experience.

(b) The director holds a bachelor's degree from an accredited institution with a chemical, physical, or biological science as his major subject and subsequent to graduation has had at least 6 years of pertinent clinical laboratory experience.

(c) The director has achieved a satisfactory grade through an examination conducted by or under the sponsorship of the U.S. Public Health Service. Such examination shall be offered annually or more often if in the Secretary's opinion the need arises, except that such examination shall no longer be conducted subsequent to July 1, 1970 (see Sec. 405. 1314 (b)). For a period ending July 31, 1967, the State agency will give interim certification of compliance with respect to a clinical laboratory if such laboratory otherwise meets the requirements and if the director has indicated his intention, in writing, to take the examination. All such interim certifications and the determinations based on them shall terminate no later than July 31, 1967; and

(ii) the State agency has evidence of successful participation of the laboratory which he directs in State-operated or State-approved proficiency testing programs meeting standards prescribed by all Secretary and covering all the specialties or subspecialties in which the laboratory performs tests for individuals enrolled under the supplementary medical insurance plan (see Subpart B of this Part 405): except that for a period ending July 31, 1968, in a State where proficiency testing programs covering some or all specialties are not yet available, the State agency will give interim certification of compliance with respect to a clinical laboratory which otherwise meets the requirements, if the laboratory successfully participates in the proficiency testing programs (if any) which the State has in operation or has approved in specialties (including the subspecially of serology) in which the laboratory performs tests, all such interim certifications terminating no later than July 31, 1968. With respect to any period after July 31, 1968, where the Secretary determines that a State does not have, or that it appears that a State will not have, acceptable proficiency testing program or programs for purposes of this paragraph, and the laboratory in such State successfully participates in the proficiency testing program(s) approved by the Secretary in specialties (including the subspecialty of serology) in which the laboratory performs tests.

(5) The director who qualified under subparagraph (4) of this paragraph may continue to qualify under the program after June 30, 1971, if: (i) The laboratory which he directs is otherwise qualified; (ii) the laboratory which he directs successfully participates in a performance evaluation program conducted by the State, meeting standards prescribed by the Secretary; and (iii) as part of the participation in the performance evaluation program, the laboratory which he directs successfully participates for at least 2 consecutive years in the 3-year period between July 1, 1968, and July 1, 1971, and annually thereafter, in a State-operated or State-approved proficiency testing program meeting standards prescribed by the Secretary, or a program approved by the Secretary as prescribed in subparagraph (4) of this paragraph in all the specialties or subspecialties in which the laboratory performs tests for individuals enrolled under the supplementary medical insurance plan (see Subpart B of this Part 405), except that if the director first qualifies under subparagraph (4) of this paragraph after July 1, 1968, but before July 1, 1971, the 3-year period for purpose of this subparagraph (5) shall begin on the date he first qualified and, if otherwise acceptable, the laboratory he directs shall be deemed qualified subject to satisfactory participation in the performance evaluation program in subdivision (ii) and this subdivision (iii) of this subparagraph within the 3-year period beginning with the date the director so qualified.

405.1313 Condition - Clinical Laboratory; Supervision. - The clinical laboratory is supervised by qualified personnel.

(a) **Standard. Supervision.** The laboratory has one or more supervisors who, under the general direction of the laboratory director, supervise technical personnel and reporting of findings, perform tests requiring special scientific skills, and, in the absence of the director, are held responsible for the proper performance of all laboratory procedures. A laboratory director is considered to be qualified as a general supervisor; therefore, depending upon the size and functions of the laboratory, the laboratory director may also serve as the laboratory supervisor. The factors explaining the standard are as follows:

(1) There are two categories of required supervisors. A general supervisor - one who meets the requirements of paragraph (b) of this section - is on the laboratory premises during all hours in which tests are being performed. A technical supervisor - one who meets the pertinent requirements of Sec. 405.1314(b) - spends an adequate amount of time in the laboratory to supervise the technical performance of the staff in his specialty and is readily available for personal or telephone consultation.

(2) A general supervisor may also be a technical supervisor.

(b) **Standard. Supervisor - qualification.** The laboratory supervisor meets the requirements of subparagraphs (1), (2), (3), (4), or (5), or (5) and (6) of this paragraph:

(1) He (i) is a physician or has earned a doctoral degree from an accredited institution with a chemical, physical, or biological science as his major subject, and (ii) subsequent to graduation has had at least 2 years' experience in one of the laboratory specialties in a clinical laboratory - with a director at the doctoral level - of a hospital, a health department, university, or medical research institution, or in a State which regulates clinical laboratory personnel, in a clinical laboratory acceptable to that State.

(2) He holds a degree of master of arts or master of science from an accredited institution with a major in one of the chemical, physical, or biological sciences and subsequent to graduation, has had at least 4 years of pertinent laboratory experience of which not less than 2 years has been spent working in the designated laboratory specialty in a clinical laboratory - with a director at the doctoral level - of a hospital, a health department, university, or medical research institution, or in a State which regulates clinical laboratory personnel, in a clinical laboratory acceptable to that State.

(3) He holds a degree of bachelor of arts or bachelor of science from an accredited institution with a major in one of the chemical, physical, or biological sciences, and, subsequent to graduation (i) has had at least 6 years of pertinent laboratory experience of which not less than 2 years has been spent working in the designated laboratory speciality in a clinical laboratory - with a director at the doctoral level - of a hospital, a health department, university, or medical research institution, or in a State which regulates clinical laboratory personnel, in a clinical laboratory acceptable to that State; and (ii) has successfully completed pertinent courses which, when combined with the foregoing experience, will provide technical and professional knowledge comparable to that of subparagraph (2) of this paragraph.

(4) He is qualified as a clinical laboratory technologist pursuant to the provisions of Sec. 405.1315 (b), (1), (2), (3), or (4), and (i) has had at least 6 years of pertinent laboratory experience of which not less than 2 years has been spent working in the designated laboratory specialty in a clinical laboratory - with a director at the doctoral level - of a hospital, university, health department, or medical research institution, or in a State which regulates clinical laboratory personnel, in a clinical laboratory acceptable to that State; and (ii) has successfully completed pertinent courses which when combined with the foregoing experience, will provide a technical and professional knowledge comparable to that of subparagraph (2) of this paragraph.

(5) For a period ending June 30, 1971, an exception to the requirements in subparagraph (1), (2), (3), or (4) of this paragraph may be made if (i) the supervisor was performing the duties of a clinical laboratory supervisor on, or within the 5 years preceding July 1, 1966, and (ii) the supervisor has had at least 15 years of pertinent clinical laboratory experience prior to July 1, 1966: Provided, That a minimum of 30 semester hours of credit toward a bachelor's degree with a chemical, physical, or a biological science as his major subject or 30 semester hours in an approved school of medical technology shall reduce the required years of experience by 2 years, with any additional hours further reducing the required years of experience at the rate of 15 hours for 1 year.

(6) The supervisor who meets the requirements under subparagraph (5) of this paragraph may continue to qualify under the program after June 30, 1971, if he has performed the duties of a supervisor for at least 2 years between July 1, 1966, and July 1, 1971, or during the 15-year qualifying period in subparagraph (5) of this paragraph: (i) In a clinical laboratory - with a director at the doctoral level - of a hospital, university, health department, or medical research institution; or (ii) in a State which regulates clinical laboratory personnel in a clinical laboratory acceptable to that State; or (iii) in a laboratory approved under the supplementary medical insurance program, Provided also, That where qualifying years in a laboratory described in (i) or (ii) of this paragraph are obtained after June 30, 1966, the laboratory meets applicable conditions under the health insurance program.

405.1315 Condition - Clinical Laboratory; Technical Personnel. - The clinical laboratory has a sufficient number of properly qualified technical personnel for the volume and diversity of tests performed.

(a) Standard; Technologist - Duties. - The laboratory employs a sufficient number of clinical laboratory technologists to proficiently perform under general supervision the clinical laboratory tests which require the exercise of independent judgment. The factors explaining the standard are as follows:

(1) The clinical laboratory technologists perform tests which require the exercise of independent judgment and responsibility, with minimal supervision by the director or supervisors, in only those specialties in which they are qualified by education, training, and experience.

(2) With respect to specialties in which the clinical laboratory technologist is not qualified by education, training, or experience, he functions only under direct supervision and performs only tests which require limited technical skill and responsibility.

(3) Clinical laboratory technologists are in sufficient number to adequately supervise the work of technicians and trainees.

(b) Standard. Technologists - qualifications. Each clinical laboratory technologist possesses a current license as a clinical laboratory technologist issued by the State, if such licensing exists, and meets the requirements of subparagraphs (1), (2), (3), (4), or (5), or (5) and (6) of this paragraph:

(1) Successful completion of a full course of study which meets all academic requirements for a bachelor's degree in medical technology from an accredited college or university.

(2) Successful completion of 3 academic years of study (a minimum of 90 semester hours or equivalent) in an accredited college or university which met the specific requirements for entrance into, and the successful completion of a course of training of at least 12 months in, a school of medical technology approved by the Council on Medical Education and Hospitals of the American Medical Association.

(3) Successful completion in an accredited college or university of a course of study which meets all academic requirements for a bachelor's degree in one of the chemical, physical, or biological sciences, and, in addition, at least 1 year of pertinent laboratory experience and/or training covering the specialty (ies) or subspecialty (ies) in which he performs tests, provided the combination has given the individual the equivalent in such specialty (ies) or subspecialty (ies) of the education and training described in subparagraph (1) or (2) of this paragraph.

(4) Successful completion of 3 years (90 semester hours or equivalent) in an accredited college or university with a distribution of courses as shown below, and, in addition successful experience and/or training covering several fields of medical laboratory work of such length (not less than 1 year), and of such quality that this experience or training, when combined with the education, will have provided the individual with education and training in medical technology equivalent to that described in subparagraph (1) or (2) of this paragraph. Distribution of course work: (Where semester hours are stated, it is understood that the equivalent in quarter hours is equally acceptable. The courses must have included lecture and laboratory work. Survey courses are not acceptable.)

(i) For those whose training was completed prior to September 15, 1963: At least 24 semester hours in chemistry and biology courses of which not less than 9 semester hours must have been in chemistry and must have included at least 6 semester hours in inorganic chemistry, and not less than 12 semester hours must have been in biology courses pertinent to the medical sciences.

(ii) For those whose training was completed after September 15, 1963: 16 semester hours in chemistry courses which included at least 6 semester hours in inorganic chemistry and

are acceptable toward a major in chemistry; 16 semester hours in biology courses which are pertinent to the medical sciences and are acceptable toward a major in the biological sciences; and 3 semester hours of mathematics.

(5) For a period ending June 30, 1971, an exception to the requirements in subparagraph (1), (2), (3), or (4) of this paragraph may be made if (i) the technologist was performing the duties of a clinical laboratory technologist on, or within the 5 years preceding, July 1, 1966, and (ii) the technologist has had at least 10 years of pertinent clinical laboratory experience prior to July 1, 1966: Provided, That a minimum of 30 semester hours of credit toward a bachelor's degree from an accredited institution with a chemical, physical or a biological science as his major subject or 30 semester hours in an approved school of medical technology shall reduce the required years of experience by 2 years, with any additional hours further reducing the required years of experience at the rate of 15 hours for 1 year.

(6) The technologist who meets the requirements under subparagraph (5) of this paragraph may continue to qualify under the program after June 30, 1971, if he has performed the duties of a clinical laboratory technologist for at least 2 years between July 1, 1966, and July , 1971, or during the 10-year qualifying period in subparagraph (5): (i) In a clinical laboratory - with a director at the doctoral level - of a hospital, university, health department, or medical research institution; or (ii) in a State which regulates clinical laboratory personnel, in a clinical laboratory acceptable to that State; or (iii) in a laboratory approved under the supplementary medical insurance program: Provided also, That where qualifying years in a laboratory described in (i) or (ii) of this paragraph are obtained after June 30, 1966, the laboratory meets applicable conditions under the health insurance program.

(c) Standard; Technician - Duties. - Clinical laboratory technicians are employed in sufficient number to meet the workload demands of the laboratory and they function only under direct supervision of a clinical laboratory technologist. The factors explaining the standard are as follows:

(1) Each clinical laboratory technician performs only those laboratory procedures which require limited technical skill and responsibility and a minimal exercise of independent judgment.

(2) No one with lesser qualifications than a clinical laboratory technician performs laboratory procedures, although manual and clerical supplemental services may be rendered by others.

(3) No clinical laboratory technician performs tests in the absence of a clinical laboratory technologist.

A Guide for Operating Ambulance Fleets

OBJECTIVE

The objective of this guide is to suggest minimum standards that the ambulance fleet operator can use as guidelines to help:

1. Prevent accidents involving his drivers.
2. Establish sound operating policies for his fleet.

PURPOSE

The purpose of this guide is to provide a tool that can be used to increase the safety and efficiency of ambulance fleet drivers and vehicles.

INTRODUCTION

The ambulance fleet operator has but one service to provide: the transportation of people. It is vitally important that this is done safely and efficiently. Safety and efficiency cannot be separated in any business. Among other things, accidents mean loss of revenue, and avoiding such loss is one of the chief functions of management.

Therefore, efficient management prevents accidents. If a job is to be done efficiently, it must be done safely.

What is included in this loss of revenue due to accidents? Let's take a quick look. Accidents occurring in ambulance fleets can be costly in terms of higher insurance premiums, profit loss due to lawsuits, permanent or temporary loss of experienced employees, the cost of management's time investigating and straightening out the accident, vehicle repair or replacement, and also in terms of poor public relations.

Sound operating policies, good driver selection and training programs, and adequate maintenance programs can help reduce accident experience

and costs. These, in turn, can increase the gross revenue of the ambulance fleet operator.

The ambulance driver must be a top professional because of the nature of his job: *he must do more than the average driver to avoid accidents.* He must be able to anticipate hazardous movements by other motorists and drive defensively in order to avoid collisions even though it is the other driver's error. In addition, he must be able to drive in a way that will not add discomfort, illness, or injury to his passengers.

It is very important, therefore, that the ambulance fleet operator use the latest techniques to select and train drivers.

Also, his vehicles must be in top mechanical condition so they operate properly at all times and can be relied upon when emergency calls are received. It is important that a regularly scheduled preventive maintenance program be established to insure peak vehicle performance.

Ambulance fleet operators should establish operating policies and put them in writing. In addition to the general operating procedures, these policies should spell out:

1. The minimum selection requirements for qualifying drivers.
2. The amount and type of training drivers should receive before they are permitted to drive an ambulance.
3. A schedule of substitute drivers in the event regularly authorized drivers are absent.

ESTABLISHING AMBULANCE FLEET OPERATING POLICY

The nature of ambulance service and the special provisions of motor vehicle regulations pertaining to it involves a responsibility for operational procedure more demanding than that of other fleet operations.

First, how is an *emergency* defined that would affect an ambulance fleet operator and second, what is an *authorized emergency vehicle?*

Definitions

1. *Emergency*—An unexpected occurrence resulting in an immediate need of attention to preserve life or lives, and/or to relieve undue suffering.

   (Of course, in this definition, good judgment is needed to determine the immediacy of the need for attention.)
2. *Authorized Emergency Vehicle*—Vehicles of the fire department (fire patrol), police vehicles and such ambulances and emergency vehicles of municipal departments or public service corporations as are designated or authorized by the commissioner or the chief of police of an

incorporated city. (Uniform Vehicle Code—Section 1-103, 1962 edition)

Receiving Information and Initial Identification of an Emergency

People become excited when confronted with unexpected illness or injury and usually don't think as clearly as they would under normal conditions.

Sketchy information given by the person calling for ambulance service can result in failure to get all the facts needed to handle the call quickly and properly. It is especially important that the person receiving the call get complete information so he can determine any unusual conditions needing special attention. However, if the call is from a physician, it should be his decision whether the case requires special attention.

To accurately identify an emergency, the ambulance fleet operator should train employees to properly handle the incoming calls and dispatch service needed. An emergency information checklist and dispatch form should be used to record information about each call. This will ensure getting all the facts, the exact location and the nature of the emergency so that the dispatcher and driver can properly evaluate the operational procedure. (See Figure 1 for a sample emergency information checklist and dispatch form.)

Dispatching Procedure

Generally, a person calling for ambulance service wants it right away, even if the nature of the illness or injury may not warrant speed.

The following is an example of effective dispatching procedure:

1. Dispatcher receives call for an ambulance.
2. Records time call was received.
3. Records information on dispatch form.
4. If an ambulance is not available for immediate dispatch when the call comes in, and the situation calls for immediate action, the dispatcher should accept the call and notify an alternate company to handle the call. Alternate ambulance facilities should be known and their telephone numbers kept on hand.
5. Dispatcher gives caller an estimated time that the ambulance will arrive.
6. Gives information on the type of emergency and location to the driver (this information should be recorded on the dispatch form).
7. Informs driver if emergency traffic regulations should be observed

2. Side streets and rural highway intersections
3. Approaching a traffic signal which is against the ambulance
4. Proper following distance
5. Passing techniques
6. Curves, hills and hidden dangers
7. Braking and acceleration

Local and state police departments may be able to provide the ambulance fleet operator with instruction in the most important aspects of each of the above subject areas. Basic data on emergency driving is provided in the North Carolina Highway Patrol's book "Police Pursuit Driving" and the U. S. Treasury Department's booklet "Pursuit Driving." (See References 14 and 23.)

VEHICLE AND EQUIPMENT MAINTENANCE

Both the ambulance and its equipment must be ready at the point of dispatch. A well-defined maintenance policy will ensure that the vehicle is in top mechanical condition at all times.

Routine preventive maintenance checks of the vehicles including brakes, steering, exhaust, emergency lights, and audible warning devices, etc., should be made each day.

Tires should also be checked carefully on a regularly scheduled program. Tire maintenance should include the following:

1. Proper inflation every time the vehicle is serviced for gas. Variation of air pressure can indicate hidden defects.
2. Careful checks for wear, cracks and scuffs at least once every 500 to 1,000 miles.
3. Rotation of the tires every 1,000 miles for maximum tire life.
4. Careful check of tire for possible replacement every 8,000 to 15,000 miles. Tire replacement should be made when the tread depth is worn to $\frac{3}{32}$'s of an inch.

During winter months, where weather conditions warrant, special duty tires, snow tires, or reinforced tire chains should be used for maximum safety. Snow tires should receive the same maintenance as regular tires. Tire chains should be checked daily when in use.

Windows must always be clean and free from all obstructions. Vehicle lights must also be kept clean and properly adjusted. Periodic

should be installed properly and visually checked periodically for signs of wear or weakness.

The emergency equipment should be checked periodically to see that it is in working order. This includes the normal first-aid emergency equipment as well as any other emergency equipment: flags, flares, fusees, other warning devices, fire extinguishing equipment.

Driver's Inspection of the Vehicle and Equipment

As each driver's shift begins, his first duty should be to inspect his vehicle and equipment to make sure they are in top operating order.

A daily vehicle and equipment inspection should include checking the tires, brakes, windows, lights, windshield wipers, gas, oil, water, heaters, battery, horn, warning devices, and 2-way radios. Any deficiencies in the vehicle, or equipment should be immediately reported to the dispatcher. (See Figure 3.)

Next, he should adjust the movable parts in the driving compartment to suit his stature. The seat should be adjusted for correct body posture, comfort, and maximum efficiency in handling the driving controls. Rear-view mirrors inside and outside must be adjusted to allow maximum sight to the rear and sides of the vehicle. Finally, the safety belt should be adjusted to fit the driver.

Preferably vehicle inspection should be completed, and the adjustments made, when the driver reports for duty and prior to his response to calls.

QUICK REMINDERS FOR POSTING AND REPETITION

Seven rules of thumb recommended in the Pennsylvania Department of Health's "Ambulance Attendant Training Pilot Project Report" (See Reference 2) can serve as reminders to ambulance drivers and might be used for posting and repeated emphasis. Basically, they are:

1. Use warning lights and siren *only* on bona fide emergency trips. They should not be used on practice runs or other non-essential trips.
2. When warning lights and siren are in use, don't assume other motorists and pedestrians will give you the right-of-way. As you drive, check other traffic to make sure other drivers are responding

(d) **Standard. Technician - qualifications.** Each clinical laboratory technician possesses a current license as a clinical laboratory technician issued by the State, if such licensing exists, and meets the requirements of subparagraphs (1), (2), (3), or (4), or (4) and (5) of this paragraph:

(1) He is a high school graduate and subsequent to graduation has completed at least 1 year in a technician training program approved by the Council on Medical Education and Hospitals of the American Medical Association or approved by the Secretary.

(2) He is a high school graduate and subsequent to graduation has served 2 years as a technician trainee in a clinical laboratory with a director at the doctoral level, or in a State which regulates clinical laboratory personnel, in a clinical laboratory acceptable to that State.

(3) He is a high school graduate and subsequent to graduation has successfully completed an official military medical laboratory procedures course of at least 50 weeks' duration, and has held, at the journeyman's level, the military enlisted occupational specialty of Medical Laboratory Specialist (Laboratory Technician).

(4) For a period ending June 30, 1971, an exception to the requirements in subparagraph (1), (2), or (3) of this paragraph may be made if (i) the technician was performing the duties of a clinical laboratory technician on, or within the 5 years preceding, July 1, 1966, and (ii) the technician has had at least 5 years of pertinent clinical laboratory experience prior to July 1, 1966: Provided, That a minimum of 30 semester hours of credit toward a bachelor's degree from an accredited institution with a chemical, physical, or a biological science as his major subject or 30 semester hours in an approved school of medical technology shall reduce the required years of experience by 2 years, with any additional hours further reducing the required years of experience at the rate of 15 hours for 1 year: And provided also, That the required 5 years of experience shall not be so reduced by more than 4 years.

(5) The technician who meets the requirements under subparagraph (4) of this paragraph may continue to qualify under the program after June 30, 1971, if he has performed the duties of a clinical laboratory technician for at least 2 years between July 1, 1966, and July 1, 1971, or during the 5-year qualifying periods in subparagraph (4): (i) In a clinical laboratory - with a director at the doctoral level - of a hospital, university, health department, or medical research institution; or (ii) in a State which regulates clinical laboratory personnel, in a clinical laboratory acceptable to that State; or (iii) in a laboratory approved under

the supplementary medical insurance program: Provided also, that where qualifying years in a laboratory described in (i) or (ii) of this paragraph are obtained after June 30, 1966, the laboratory meets applicable conditions under the health insurance program.

9. Follow-up

F. Other Filing Systems

Supplemental Teaching Aids:

Good resource people for this unit are school librarians or bank employees. A visit to a local library to observe its filing system is useful also.

The following are good resource books for the unit; Business Filing and Records Control, 3rd ed., Ernest D. Brasett, South-Western, Cincinnati, 1963, Records Management, Mary C. Griffin, Allyn and Bacon, Boston, 1964, and Gregg Quick Filing Practice, McGraw-Hill, New York, 1965.

A useful programmed instruction book is Basic Rules of Alphabetic Filing, by Fahrner and Gibbs, South-Western, Cincinnati, 1965. Free or inexpensive pamphlets are available from Smead Manufacturing Co., Hastings, Minnesota (Do's & Dont's of Filing and Science of Filing), and from the Oxford Filing Supply Company, Inc., Garden City, N. Y. 11533(33 Common Filing Questions.) Remington Rand, Systems Division has the film "It must be somewhere", while Cornet Films has "Filing Procedures in Business".

Training Time 15-20 hours

2242

STANDARD REPORT OF ALCOHOL INVOLVEMENT IN FATAL MOTOR VEHICLE TRAFFIC ACCIDENTS

This form is intended to record the extent of alcohol involvement in FATAL Motor Vehicle Accidents. It is restricted to drivers and pedestrians, 15 years or older, who die within 4 hours of an accident. This includes ALL reported traffic fatalities, not only those tested for alcohol. Thus, it is to include results of post-mortem examinations and the results of ante-mortem studies in hospitals and clinics. However, no case in which post-accident survival was 4 hours or more is to be included. This form should not be completed on the basis of the final legal disposition of the cases, but, rather, on the basis of the considered judgment of the person completing it.

OFFICE OF RECORD _____ STATE _____
(Coroner, Health Dept., etc.)

REPORT PREPARED BY _____ DATE _____

REPORT COVERS CASES DATING FROM _____ TO _____

TYPE OF FATALITY			TOTAL DEATHS WITHIN 4 HOURS	NUMBER TESTED FOR ALCOHOL	NO. OF CASES IN EACH RANGE OF ALCOHOL CONCENTRATION					
					NEGA-TIVE	0.01 - 0.04%	0.05 - 0.09%	0.10 - 0.14%	0.15 - 0.24%	OVER 0.25%
PEDESTRIANS	AGED	15-64								
		65 --								
		TOTAL								
DRIVERS	CATEGORIES (*)	A								
		B								
		C								
		D								
		E								
		F								
		G								
		TOTAL								

(*) A. Only one vehicle involved – its driver fatally injured.
B. More than one vehicle involved, but only one in motion – its driver fatally injured.
C. More than one vehicle involved, but only one in motion – driver of nonmoving vehicle fatally injured.
D. More than one vehicle involved and in motion – driver in responsible vehicle fatally injured.
E. More than one vehicle involved and in motion – driver in nonresponsible vehicle fatally injured.
F. More than one vehicle involved and in motion – responsibility of fatally injured driver unknown or not clear.
G. More than one vehicle involved and in motion – two or more drivers fatally injured.

With respect to Categories D,E,F, and G above, the following explanations are offered:

- D should be chosen where there would be no reasonable doubt as to which driver or vehicle was responsible for an accident due to the dynamics of the crashes involved. An example might be a driver who crosses a median strip and hits an innocent driver, killing himself.
- E should be chosen if, in the example given above, the innocent driver is killed rather than the crossing driver.
- F should be chosen where there is no clear evidence which driver was at fault.
- Each driver killed in the G Category should be listed in the appropriate column of the form.

ABSTRACT - To provide a tool that can be used to increase the safety and efficiency of ambulance fleet drivers and vehicles, this guide was developed by the National Safety Council. The objective is to suggest minimum standards that the ambulance fleet operator can use as guidelines to help in preventing accidents involving his drivers and in establishing sound operating policies for his fleet. Topics are: (1) Establishing Operating Policy, (2) Selection of Drivers, (3) Driver Instruction, (4) Special Requirements of Ambulance Driving, (5) Emergency Vehicle Driving, (6) Vehicle and Equipment Maintenance, and (7) Quick Reminders for Posting and Repetition. References, a model ordinance, and a uniform vehicle code are appended. (GB)

A Guide for Operating Ambulance Fleets

OBJECTIVE

The objective of this guide is to suggest minimum standards that the ambulance fleet operator can use as guidelines to help:

1. Prevent accidents involving his drivers.
2. Establish sound operating policies for his fleet.

PURPOSE

The purpose of this guide is to provide a tool that can be used to increase the safety and efficiency of ambulance fleet drivers and vehicles.

INTRODUCTION

The ambulance fleet operator has but one service to provide: the transportation of people. It is vitally important that this is done safely and efficiently. Safety and efficiency cannot be separated in any business. Among other things, accidents mean loss of revenue, and avoiding such loss is one of the chief functions of management.

Therefore, efficient management prevents accidents. If a job is to be done efficiently, it must be done safely.

What is included in this loss of revenue due to accidents? Let's take a quick look. Accidents occurring in ambulance fleets can be costly in terms of higher insurance premiums, profit loss due to lawsuits, permanent or temporary loss of experienced employees, the cost of management's time investigating and straightening out the accident, vehicle repair or replacement, and also in terms of poor public relations.

Sound operating policies, good driver selection and training programs, and adequate maintenance programs can help reduce accident experience

22796

Local and state police departments may be able to provide the ambulance fleet operator with instruction in the most important aspects of each of the above subject areas. Basic data on emergency driving is provided in the North Carolina Highway Patrol's book "Police Pursuit Driving" and the U. S. Treasury Department's booklet "Pursuit Driving." (See References 14 and 23.)

VEHICLE AND EQUIPMENT MAINTENANCE

Both the ambulance and its equipment must be ready at the point of dispatch. A well-defined maintenance policy will ensure that the vehicle is in top mechanical condition at all times.

Routine preventive maintenance checks of the vehicles including brakes, steering, exhaust, emergency lights, and audible warning devices, etc., should be made each day.

Tires should also be checked carefully on a regularly scheduled program. Tire maintenance should include the following:

1. Proper inflation every time the vehicle is serviced for gas. Variation of air pressure can indicate hidden defects.
2. Careful checks for wear, cracks and scuffs at least once every 500 to 1,000 miles.
3. Rotation of the tires every 1,000 miles for maximum tire life.
4. Careful check of tire for possible replacement every 8,000 to 15,000 miles. Tire replacement should be made when the tread depth is worn to $\frac{3}{32}$'s of an inch.

During winter months, where weather conditions warrant, special duty tires, snow tires, or reinforced tire chains should be used for maximum safety. Snow tires should receive the same maintenance as regular tires. Tire chains should be checked daily when in use.

Windows must always be clean and free from all obstructions. Vehicle lights must also be kept clean and properly adjusted. Periodic checks of the headlights for proper adjustment can easily be incorporated into the scheduled preventive maintenance checks.

7. Braking and acceleration

incorporated city. (Uniform Vehicle Code—Section 1-103, 1962 edition)

Receiving Information and Initial Identification of an Emergency

People become excited when confronted with unexpected illness or injury and usually don't think as clearly as they would under normal conditions.

Sketchy information given by the person calling for ambulance service can result in failure to get all the facts needed to handle the call quickly and properly. It is especially important that the person receiving the call get complete information so he can determine any unusual conditions needing special attention. However, if the call is from a physician, it should be his decision whether the case requires special attention.

To accurately identify an emergency, the ambulance fleet operator should train employees to properly handle the incoming calls and dispatch service needed. An emergency information checklist and dispatch form should be used to record information about each call. This will ensure getting all the facts, the exact location and the nature of the emergency so that the dispatcher and driver can properly evaluate the operational procedure. (See Figure 1 for a sample emergency information checklist and dispatch form.)

Dispatching Procedure

Generally, a person calling for ambulance service wants it right away, even if the nature of the illness or injury may not warrant speed.

The following is an example of effective dispatching procedure:

1. Dispatcher receives call for an ambulance.
2. Records time call was received.
3. Records information on dispatch form.
4. If an ambulance is not available for immediate dispatch when the call comes in, and the situation calls for immediate action, the dispatcher should accept the call and notify an alternate company to handle the call. Alternate ambulance facilities should be known and their telephone numbers kept on hand.
5. Dispatcher gives caller an estimated time that the ambulance will arrive.
6. Gives information on the type of emergency and location to the driver (this information should be recorded on the dispatch form).
7. Informs driver if emergency traffic regulations should be observed

INFORMATION AND DISPATCH FORM

1. Date _____ Time _____ a.m. p.m.

2. Name _____ (of person calling)

   Telephone No. _____

3. From _____ (address where patient is)

   _____

   _____

   To _____ (destination of patient)

   _____

   _____

4. Type of Emergency
   - ☐ Vehicle Collision
   - ☐ Illness
   - ☐ Other _____

5. Description of Emergency
   - ☐ Bodily Injury
   - ☐ Heart Attack
   - ☐ Drowning
   - ☐ Poisoning
   - ☐ Bleeding
   - ☐ Stroke
   - ☐ Convulsion
   - ☐ Heat Stroke
   - ☐ Other: _____

6. Type of Driving
   - ☐ Routine call—Observe all traffic regulations
   - ☐ Unusual call—Avoid unnecessary delays but waive traffic regulations *only* when necessary and then only with great caution

7. Driver: _____

   Attendant: _____

8 Remarks: _____

9. Dispatcher: _____ Dispatch Time: _____ a.m. p.m.

UNIT XI (14.0703-05)

SOURCES OF INFORMATION

Performance Objectives:

Upon completion of this unit the student will be able to demonstrate her knowledge of information sources by compiling a list of information to meet specifications designated by the instructor.

Unit Outline:

A. Reference Books as a Tool of the Office Worker

1. Importance of accurate business information

2. Kinds of information needed

3. Necessity of obtaining information quickly

4. Necessity for initiative in finding information

B. Reference Books of the Office Worker

1. Dictionaries

2. Reference manual for stenographers and typists

3. English grammar and style books

4. Directories

5. Thesaurus

C. Other Sources of Factual Information

Supplemental Teaching Aids:

The most obvious resource pereon is of course the librarian. Also available is the Gregg Secretarial Record #6, and Set #2 Finding Needed Information. The film "Look It Up-Dictionary Habits" (11 min.) is available from Cornet Instructional Films.

Training Time 3-5 hours

(for details: "En Route to and From Scene of Emergency" and "Appendix C").

8. Records time ambulance was dispatched.
9. Makes sure that medical care is available to patient upon arrival at the hospital, or other destination.
10. Notifies police agencies concerned of an emergency run that occurs in their respective territories. (Many times police agencies become involved in emergency calls, especially in cases of automobile accidents. If the ambulance dispatcher notifies the police, and vice versa, each will know if the other is en route to the emergency scene. Where both are using sirens, this procedure may help prevent collisions between the police vehicle and the ambulance. Hopefully, neither driver will depend on his siren to guarantee his right-of-way and will observe traffic regulations.)

Dispatcher Control Over Drivers and Vehicles

It is very important that the dispatcher knows where his drivers and units are at all times and what they are doing so that he knows exactly what units are available or likely to be on standby. This information will also make it easier for the dispatcher to schedule routine assignments such as moving a patient from his home to a hospital or from one hospital to another.

Dispatchers should be able to tell accurately if the driver waived or observed traffic regulations according to instructions. This is based on time it takes to arrive at the location compared with the time he was dispatched.

The following procedure will give the dispatcher control over drivers and vehicles:

1. The driver radios or calls when he arrives at the destination to pick up a patient.
2. Unusual delays or circumstances should be reported at time of arrival at pickup location.
3. Driver radios or calls both when he arrives at and clears the final destination for possible in-service rescheduling.

The time of each call should be recorded on the master dispatch form.

Complete control of the driver and the driving situation by some ambulance agencies is obtained by requiring that drivers radio to get permission to use the siren, to exceed speed limits, or to waive certain operating precautions. If an ambulance crew arrives at the scene of an emergency and finds conditions worse than first thought to be, the driver radios this information to the dispatcher. The dispatcher then decides

AMBULANCE SIREN REPORT

ORDERED BY_____

Figure 2—Sample ambulance siren report.

whether or not the siren should be used and any other precautionary measures should be taken. This can be documented by using an ambulance siren report. (See Figure 2.)

Another control device used by some ambulance operators is the Tachograph: a mechanical device that records vehicle speeds and non-moving intervals in relation to the time of day. The dispatcher can check the speed recorded on the Tachograph with the route through which the driver traveled. If unnecessary speeds are identified, the driver should be cautioned against abusive use of emergency running time and the dangers involved should be impressed upon him.

En Route to and From Scene of Emergency

Through the years, high speed and chance-taking have been associated with ambulance service. Flashing emergency lights and sirens to warn motorists lead to a false sense of security. Often when other drivers fail to heed such devices and fail to follow the regulations, serious accidents have resulted. It is not the purpose of emergency equipment, flashing lights and sirens, to aid the driver in exceeding speed limits, but to keep the ambulance moving at a safe and constant speed.

In recent years the need for speed, the emergency right-of-way, and use of sirens and flashing lights has been seriously challenged by physicians and ambulance fleet operators.

A one-year study conducted in New York City showed that accidents were reduced by one-third when ambulance drivers obeyed traffic regulations and did not use sirens. This reduction occurred even though more than twice as many calls were answered during that year than in previous years. Another part of this study revealed that one of the major causes of ambulance accidents was the reliance that drivers placed on a siren to give them the right-of-way. (See References 11 and 16.)

A study of ambulance accident cases conducted by the National Safety Council in 1961 supported the New York City findings regarding accident causes and the unsatisfactory reliance placed on the siren and flashing emergency lights by ambulance drivers to clear a path for them. (See Reference 7.)

The use of speed in answering emergency calls was questioned by physicians Curry and Lyttle, Flint, Mich., in their study of 2,500 Flint city ambulance runs. Their findings showed that *haste in transporting the injured was unnecessary in 98.2 per cent of the cases.* In the other cases, expeditious handling was considered necessary, but a speeding ambulance could have *increased* the severity of the injuries.

From their study they concluded that, *except in rare cases,* speed is not necessary and that traffic regulations and control devices should be followed when going to and from an emergency scene. (See References 3 and 12.)

Prompt responses to a call and prompt first-aid treatment at the scene usually eliminates the need for excessive speed.

At the Emergency Scene

When the driver arrives at the emergency scene he should park the ambulance close enough to facilitate handling the patient and to minimize interference with traffic.

Standard Emergency Equipment

Each ambulance should carry adequate equipment, as recommended by the Committee on Trauma of the American College of Surgeons, for dressing wounds, splinting fractures, controlling hemorrhage, and resuscitation. (See Reference 18.)

Other Useful Equipment

Rescue equipment that has been helpful, in addition to medical aid, are the tools needed to gain entry into a smashed vehicle. These include pry bars, tow cable (about 50 feet long), a dry chemical, multi-purpose

fire extinguisher, and other devices. When this equipment is carried, it should be stored in a place where it will not come in contact with sterile equipment in the ambulance.

Routing

Planned routing, because it establishes the best and most direct routes to various sectors of an area, will save time when going to the scene of an emergency. It will also reduce the possibility of a driver's being delayed by slow moving traffic or routes normally congested during certain periods of the day.

A plan for routing should include:

1. Dividing the area into sections.
2. Test runs conducted over the selected routes during peak traffic hours of the day and night to determine alternate routes available.
3. Test runs (not in ambulance vehicles, necessarily, and *never* with emergency lights or siren on) should be made at regular intervals. This will determine possible new routes, community construction that may cause heavier traffic, congestion or reduced speed areas of operation.
4. Maintaining an up-to-date area map.
5. A trip report following each service call that reveals new information to keep the route map up to date.

If a community ambulance fleet is of a size that warrants assigning each driver to a particular area of the city, each driver should be trained to be familiar with the streets and traffic patterns in his area. In smaller cities, drivers should be well acquainted with the entire street system. Whether the city served is large or small, alternate routes should be planned in case regular routes are blocked.

SELECTION OF DRIVERS OR ATTENDANT DRIVERS

Personal supervision of an ambulance driver is usually impossible once he is dispatched. Control of a driver, however, begins with his selection. Since ambulance driving is specialized, it is very important that the fleet employ only the very best of drivers.

Qualities of a prospective driver that can be checked and will help predict whether or not he will be a good driver include:

1. Ability in the driving task. Can the applicant operate a motor vehicle efficiently?
2. Are his physical qualifications acceptable?

3. Does he have a proper driving attitude?
4. Does he have the ability to recognize and anticipate possible accident-producing situations?
5. Is he emotionally stable, and does he have good character traits?

Four elements of the selection screening are related directly to driving. A thorough check of these conditions is the first step in selecting a good driver.

1. Driving Experience
   a. Type of vehicle—What type of vehicle has the applicant driven? For how long?
   b. What type of operator's license does he have?
   c. Type of driving job—What type of driving did the applicant previously perform?
2. Past Driving Record
   a. Violations—What is the applicant's history of traffic violations in both his personal and professional driving?
   b. Accidents—Has the applicant been involved in any? How many and what was the nature and cause of each? Were these preventable or not?
3. Previous Driver Instruction
   a. Classroom—Did the applicant receive formal classroom driving instruction? How much? Professional driver training? Did previous employer conduct training? Did the applicant receive high-school driver education training?
   b. Behind-the-wheel—Has the applicant had any behind-the-wheel driver training? What types of vehicles? How much? Did previous employer conduct driver training?
4. Physical Fitness
   a. Physical examination—Is a physical examination made before the applicant is hired? Is a periodic physical exam required thereafter?
   b. Minimum standards prescribed by the American Medical Association—Does the applicant meet minimum standards? (See Reference 17.) If not, are there any corrective measures that can be taken to bring him up to the standards? Are corrective glasses, medication, or treatments indicated?

Important sources of information which should be thoroughly checked to determine the applicant's emotional stability and character are his past employment record, his credit references, and personal references.

There are three types of tests that help to determine the applicant's

attitude behind the wheel and his ability to recognize and anticipate possible accident-producing situations. These tests are:

1. Traffic and driving knowledge tests. (For example, see Reference 21.)
2. Driving skill tests. (For example, see Reference 27.)
3. Attitude tests. (For example, see Reference 25.)

(NOTE: Attitude tests are still questioned as to their reliability and validity in predicting individual performance.)

Tests such as these can be very helpful in the driver selection process if they are used along with the steps previously discussed.

DRIVER INSTRUCTION

Once the applicant has been screened fully and employed, the next step is indoctrination. Ambulance driving is a specialized skill requiring special driving instruction.

Driver instruction consists of two parts: classroom instruction and behind-the-wheel training. The following outline lists suggests minimum instruction for trainees.

1. Classroom instruction
   a. Orientation
      (1) General description of the driver-training program and its content.
      (2) The traffic problem and its relation to accidents. (See Reference 13.)
      (3) The nature of the job and the problems connected with ambulance driving.
      (4) Description of the fleet safety program.
      (5) Discussion of the areas serviced by the fleet with attention to routes and hazards that might be encountered along these routes.
      (6) Instructions on the use and filling out of necessary forms and records.
   b. Physical laws and their effect on driving. (See Reference 13.)
      (1) Centrifugal force
      (2) Gravity
      (3) Kinetics
      (4) Friction
   c. Safe driving rules and regulations. (See References 13, 22 and 27.)

22805

(1) How the law provides special conditions.

(2) What is expected of the ambulance driver because of special conditions.

d. Laws and ordinances

(1) General—Local and state traffic regulations.

(2) Specific—Laws and ordinances for emergency vehicles. (See References 20 and 28.)

e. First-aid training. (See References 2, 8, 9 and 10.) Both drivers and attendants should be able to render first aid equivalent to the advanced American Red Cross course or the advanced United States Bureau of Mines first-aid qualifications. (The Committee on Trauma of the American College of Surgeons also recommends that annual first-aid refresher courses be given.)

2. Behind-the-wheel training

a. Basic driving skills. (See Reference 13.)

b. Emergency driving skills. (See "Emergency Vehicle Driving" Section of the Guide.)

SPECIAL REQUIREMENTS OF AMBULANCE DRIVING

It is very important that each new trainee be taught the special requirements of driving an ambulance and that he receives specific training in driving an ambulance.

As an introduction, the trainee might ride as a third man on an ambulance for a number of runs to observe how the general public reacts to sirens, red flashing lights, and the ambulance in general. In addition, the trainee might be placed on the emergency stretcher or cot in the ambulance while a skilled driver proceeds over a designated course so potential driver can feel the affects of riding in an ambulance. NOTE: This should *not* be done with siren or warning lights on. All traffic regulations should be observed.

The physical laws that affect an ambulance braking system and stopping distance must be related to the care and treatment of patients. Kinetic energy of a moving vehicle in relation to friction and gravity all come into play when bringing a vehicle to a stop. Friction and gravity tend to hold the vehicle to a given course. They can be overcome by the speed of the vehicle and its course. Abrupt changes tend to take control from the driver and involve uncomfortable conditions for the patient. (See Reference 13.)

Initial and repeated instruction is needed concerning physical changes

which are created by bad weather and slippery road conditions. The trainee must be thoroughly familiar with the effects of slippery road surfaces on stopping distances and other maneuvers of his vehicle. The relationship of visibility to operating speeds is also important to emphasize in training.

Roadside environment (such as buildings, and commercial and recreational areas) and conflicting traffic movement on the streets, plus the condition of the road (curves, chuck holes, and hills) can all contribute to the problems of ambulance driving. Driving should be adjusted accordingly.

Problems of driving an ambulance can also be affected by such conditions as the driver's health and emotional condition, which can change from day to day. Both driver and his supervisor must be taught to recognize these changes and to make necessary adjustments.

An angry or upset driver, or a physically unfit driver does not have his normal ability for quick decisions or react normally to situations that may require responses necessary under stress conditions. Unusual displays of anger or nervousness on the part of a driver should be considered clues to emotional stress. In such instances, it might be well to remove him from the driving roster because he might possibly be involved in an accident. This can inconvenience the ambulance fleet at the time, but it could save expense and trouble in the long run.

EMERGENCY VEHICLE DRIVING

Although it should be avoided as much as possible, when it is necessary to operate the ambulance at speeds over the posted limit, the ambulance driver should receive thorough specialized training. Emergency operation demands a high degree of skill, knowledge of the physical laws governing motor vehicle operation, rules of the road, eyesight, knowledge of the streets where the driving will be done, judgment, and experience. It should never be expected of the novice.

Previous driving experience must be considered in assigning "emergency" runs to new drivers. It takes much training to be prepared to make the important decisions required in ambulance driving. (See Reference 14.)

Specialized Instruction in Emergency Vehicle Driving

Specialized Instruction in the proper techniques of emergency driving should be given in at least the following:

1. Right-of-way (which is never guaranteed)

should be installed properly and visually checked periodically for signs of wear or weakness.

The emergency equipment should be checked periodically to see that it is in working order. This includes the normal first-aid emergency equipment as well as any other emergency equipment: flags, flares, fusees, other warning devices, fire extinguishing equipment.

Driver's Inspection of the Vehicle and Equipment

As each driver's shift begins, his first duty should be to inspect his vehicle and equipment to make sure they are in top operating order.

A daily vehicle and equipment inspection should include checking the tires, brakes, windows, lights, windshield wipers, gas, oil, water, heaters, battery, horn, warning devices, and 2-way radios. Any deficiencies in the vehicle, or equipment should be immediately reported to the dispatcher. (See Figure 3.)

Next, he should adjust the movable parts in the driving compartment to suit his stature. The seat should be adjusted for correct body posture, comfort, and maximum efficiency in handling the driving controls. Rear-view mirrors inside and outside must be adjusted to allow maximum sight to the rear and sides of the vehicle. Finally, the safety belt should be adjusted to fit the driver.

Preferably vehicle inspection should be completed, and the adjustments made, when the driver reports for duty and prior to his response to calls.

QUICK REMINDERS FOR POSTING AND REPETITION

Seven rules of thumb recommended in the Pennsylvania Department of Health's "Ambulance Attendant Training Pilot Project Report" (See Reference 2) can serve as reminders to ambulance drivers and might be used for posting and repeated emphasis. Basically, they are:

1. Use warning lights and siren *only* on bona fide emergency trips. They should not be used on practice runs or other non-essential trips.

2. When warning lights and siren are in use, don't assume other motorists and pedestrians will give you the right-of-way. As you drive, check other traffic to make sure other drivers are responding to your signals correctly.

3. If it is necessary to go through a red light, approach the corner cautiously and slowly. The siren and light must be functioning

Auto Damage Correction Occupations; A Suggested Outline of Service and Levels for the Automotive Industries Occupations. Special Field Test Edition.

New York State Education Dept., Albany. Bureau of Continuing Education Curriculum Services.
MF AVAILABLE IN VT-ERIC SET.
The Publications Distribution Unit, State Education Department, Albany, New York 12224 (single copies only).
PUB DATE - 69 57p.

DESCRIPTORS - *CURRICULUM GUIDES; *AUTO BODY REPAIRMEN; *AUTO MECHANICS (OCCUPATION); *SKILLED OCCUPATIONS; REPAIR; *TRADE AND INDUSTRIAL EDUCATION; SKILLED WORKERS

ABSTRACT - This curriculum guide is intended to assist instructors in identifying and organizing the course content necessary to prepare trainees for entry employment in the field of auto damage correction services. Based on services to be performed, content is divided into the major areas of General Services, Paint, Body, and Frame, with the instructional material for each area presented in outline form for basic, intermediate, and advanced levels. Outlines include: (1) level, (2) topics to be covered, (3) concepts to be developed, (4) teaching suggestions, and (5) applications. A bibliography and a listing of occupations ranging from entry to technical level within the field of auto damage correction are provided. (AW)

VT 011 920

well in advance of the crossing. Do not proceed through until you are sure all other traffic is stopped.

4. The use of siren and warning light should be used with discrimination.

5. Do not exceed the speed limits posted or dictated by weather and traffic conditions except under extreme conditions.

6. In unfavorable weather conditions such as ice, snow, or rain, always reduce speeds. Use snow tires or reinforced tire chains when necessary.

7. Don't endanger your own life and the lives of your patients. Many instances of D.O.A. have been caused by *poor* ambulance service and unnecessary chance-taking.

SUMMARY

Much has been learned about accident prevention in motor vehicle fleets which has resulted in the improvement of fleet operations and a savings of lives and dollars.

Standards of performance, established by the National Safety Council, when conscientiously applied, have proven extremely effective in reducing accidents. These standards provide a measure of driving performance that should be the goal of every successful fleet operation. These standards also provide a means of continuous in-service training in the techniques of defensive driving.

The four elements of a minimum fleet safety program include:

1. Set Standards—show drivers what is expected of them.
2. Show Them How—demonstrate how to meet the standards.
3. Keep Score—through complete accident records to determine whether drivers are meeting these standards.
4. Motivate—to show appreciation to drivers for doing a good job when they have met the standards.

The recommendations in this guide will help the ambulance fleet operator carry out the elements of a basic fleet safety program and will aid him in providing safe and efficient ambulance service. Other elements standard to all commercial driving have as much application to the ambulance fleet as to any other well-managed fleet operation.

22811

Uniform Vehicle Code Sections Pertaining to Emergency Vehicles

Sec. 1-103—Authorized emergency vehicle—Vehicles of the fire department (fire patrol), police vehicles and such ambulances and emergency vehicles of municipal departments or public service corporations as are designated or authorized by the commissioner (or the chief of police of an incorporated city).

Sec. 11-106—Authorized emergency vehicles

(a) The driver of an authorized emergency vehicle, when responding to an emergency call or when in the pursuit of an actual or suspected violator of the law or when responding to (but not upon returning from) a fire alarm, may exercise the privileges set forth in this section, but subject to the conditions herein stated.

(b) The driver of an authorized emergency vehicle may:

1. Park or stand, irrespective of the provisions of this chapter;
2. Proceed past a red or stop signal or stop sign, but only after slowing down as may be necessary for safe operation;
3. Exceed maximum speed limits so long as he does not endanger life or property; (Revised, 1956)
4. Disregard regulations governing direction of movement or turning in specified directions.

(c) The exemptions herein granted to an authorized emergency vehicle shall apply only when such vehicle is making use of audible and visual signals meeting the requirements of Sec. 12-218 of this act, except that an authorized emergency vehicle operated as a police vehicle need not be equipped with or display a red light visible from in front of the vehicle. (Revised, 1954)

(d) The foregoing provisions shall not relieve the driver of an authorized emergency vehicle from the duty to drive with due regard for the safety of all persons, nor shall such provisions protect the driver from the consequences of his reckless disregard for the safety of others.

Sec. 11-405—Operation of vehicles and streetcars on approach of authorized emergency vehicles

(a) Upon the immediate approach of an authorized emergency vehicle making use of audible and visual signals meeting the requirements of Section 12-218 of this act, or of a police vehicle properly and lawfully making use of an audible signal only: (Revised, 1954)

1. The driver of every other vehicle shall yield the right-of-way and shall immediately drive to a position parallel to, and as close as possible to the right-hand edge or curb of the roadway clear of any intersection and

LTRS 22812

shall stop and remain in such position until the authorized emergency vehicle has passed, except when otherwise directed by a police officer.

2. Upon the approach of an authorized emergency vehicle, as above stated, the motorman of every streetcar shall immediately stop such car clear of any intersection and keep it in such position until the authorized emergency vehicle has passed, except when otherwise directed by a police officer.

(b) This section shall not operate to relieve the driver of an authorized emergency vehicle from the duty to drive with due regard for the safety of all persons using the highway.

Sec. 11-504—Drivers to exercise due care—Notwithstanding the foregoing provisions of this chapter every driver of a vehicle shall exercise due care to avoid colliding with any pedestrian upon any roadway and shall give warning by sounding the horn when necessary and shall exercise proper precaution upon observing any child or any obviously confused or incapacitated person upon a roadway. (Revised, 1962)

Sec. 12-218—Audible and visual signals on vehicles

(a) Every authorized emergency vehicle shall, in addition to any other equipment and distinctive markings required by this act, be equipped with a siren, exhaust whistle, or bell capable of giving an audible signal.

(b) Every school bus and every authorized emergency vehicle shall, in addition to any other equipment and distinctive markings required by this act, be equipped with signal lamps mounted as high and as widely spaced laterally as practicable, which shall be capable of displaying to the front two alternately flashing red lights located at the same level, and these lights shall have sufficient intensity to be visible at 500 feet in normal sunlight. (Revised, 1962)

(c) A police vehicle when used as an authorized emergency vehicle may, but need not, be equipped with alternately flashing red lights specified herein.

(d) The alternately flashing lighting described in subsections (b) and (c) of this section shall not be used on any vehicle other than a school bus or an authorized emergency vehicle. (New, 1962)

(e) The use of the signal equipment described herein shall impose upon drivers of other vehicles the obligation to yield the right-of-way and stop as prescribed in Sections 11-405 and 11-707 of this act. (New, 1954)

Sec. 12-401—Horns and warning devices

Paragraph (d)—Any authorized emergency vehicle may be equipped with a siren, whistle or bell, capable of emitting sound audible under normal conditions from a distance of not less than 500 feet and of a type approved by the department, but such siren shall not be used except when such vehicle is operated in response to an emergency call or in the immediate pursuit of an actual or suspected violator of the law, in which said latter events the driver of such vehicle shall sound said siren when reasonably necessary to warn pedestrians and other drivers of the approach thereof.

22813

APPENDIX "B"

A Model Ordinance or Statute Regulating Ambulance Service

INTRODUCTION

Development of this model ordinance or statute began in 1956 when representatives of the medical profession concluded that the medical profession had taken too little interest in preventing trauma, while those responsible for traffic safety were too little concerned with the human salvage operations of the doctors. This resulted in a Joint Action Program sponsored by: American College of Surgeons, American Association for the Surgery of Trauma, and National Safety Council.

Late in 1959 the policy committee of this group asked the Traffic Conference to develop a model ordinance or statute relating to the transportation of the injured. A special Conference Committee, representing the interests involved and including a legal consultant, was activated.

The ordinance or statute published here was developed after a number of meetings of the committee, and extensive correspondence with many interested groups. Numerous city ordinances and the National Institute of Municipal Law Officers' model were used as a guide. At the October 28, 1962, meeting of the special Conference Committee, representatives of many ambulance associations throughout the country offered several excellent suggestions which were incorporated. The model was approved, although not unanimously, by the Traffic Conference Executive Committee on April 3, 1963.

It was concluded at this meeting that such a regulation would be more effective if it became a state law. Therefore, the draft is designed so that, with appropriate changes, it may be used also as a Model Statute. Where feasible, a state statute is preferable to a local ordinance.

In Section 2, "Licensing Requirements," it is presumed that where the model is used as an ordinance, the city or county has legal authority under state law to adopt special license requirements for ambulances. The legal assumption, which should be verified in each case, is that the city or county has authority under its police power to prescribe regulations necessary to supplement state laws where the public safety and welfare so require. Therefore, it should be expressly understood that, in any state, the model, when adopted as an ordinance, must be modified to eliminate any conflict with existing state laws.

The intent of the model is to serve as a guide to improve a necessary public service and provide uniformity throughout the United States.

92815

DRAFT OF ORDINANCE

An Ordinance to Regulate the Licensing, Inspection, and Operation of Ambulances, to Provide Standards for the Licensing of Ambulances and of Ambulance Drivers, Attendants, and Attendant-Drivers, to Provide for Renewal and Revocation of Licenses, to Require Written Records and Reports, to Provide for Traffic Regulation of Ambulances, and to Establish Penalties for Violation of its Provisions.

The (_____) of (_____)
enacting body — city or county

ordains as follows:

SECTION 1 **Definitions.**

(a) Unless otherwise specified, the term "Ambulance" means any privately- or publicly-owned motor vehicle that is specially designed or constructed, and equipped, and is intended to be used for, and is maintained or operated for the transportation of patients, including dual-purpose police patrol cars and funeral coaches or hearses which otherwise comply with the provisions of this Ordinance.

(b) "Attendant" means a trained and/or qualified individual responsible for the operation of an ambulance and the care of the patients whether or not the attendant also serves as driver.

(c) "Attendant-Driver" means an individual who is qualified as an attendant and a driver.

(d) "Driver" means an individual who drives an ambulance.

(e) "Dual-purpose police patrol car" means a vehicle, operated by a police department, that is equipped as an ambulance, even though it is also used for patrol or other police purposes.

(f) "Health Officer" means the (_____city or county_____) Health Officer or other designated official.

(g) "License Officer" means the (_____city or county_____) (_____designated officer_____).

(h) "Patient" means an individual who is stick, injured, wounded, or otherwise incapacitated or helpless.

(i) "Person" means any individual, firm, partnership, association, corporation, company, group of individuals acting together for a common purpose or organization of any kind, including any governmental agency other than the United States.

SECTION 2 **License Required***

(a) No person, either as owner, agent, or otherwise, shall furnish, operate, conduct, maintain, advertise, or otherwise be engaged in or profess to be engaged in the

---

*These licensing requirements are based on the presumption that the city or county has legal authority under State law to adopt such special license requirements for ambulances. The legal assumption, which should be verified in each cases, is that the city or county has authority under its police power to prescribe regulations necessary to supplement State laws where the public safety and welfare so require.

22816

business or service of the transportation of patients upon the streets, alleys, or any public way or place of (_____city or county_____) unless he holds a currently valid license for an ambulance, issued pursuant to this Ordinance. An ambulance operated by an agency of the United States shall not be required to be licensed hereunder.

(b) No ambulance shall be operated, and no individual shall drive, attend or permit it to be operated on the streets, alleys, or any public way or place of (_____city or county_____) unless it shall be under the immediate supervision and direction of a person who is holding a currently valid license as an attendant-driver or attendant.

(c) *Provided however,* that no such licenses shall be required for an ambulance, or for the driver or attendant-driver of an

(i) ambulance, which is rendering assistance to licensed ambulances in the case of a major catastrophe or emergency with which the licensed ambulances of (_____city or county_____) are insufficient or unable to cope; or

(ii) is operated from a location or headquarters outside of (_____city or county_____) in order to transport patients who are picked up beyond the limits of (_____city or county_____) to locations within (_____city or county_____), or to transport patients who are picked up within (_____city or county_____) to locations beyond the limits of (_____city or county_____) but no such outside ambulance shall be used to pick up patients within (_____city or county_____) for transportation to locations within (_____city or county_____) unless the driver, attendant and attendant-driver and the person subject to the provisions of Section 2(a) of this Ordinance in respect of such ambulance, hold currently valid licenses issued pursuant to this Ordinance.

SECTION 3 **Application for Ambulance License.** Applications for ambulance licenses hereunder shall be made upon such forms as may be prepared or prescribed by the License Officer and shall contain:

(a) The name and address of the applicant and the owner of the ambulance.

(b) The trade or other fictitious name, if any, under which the applicant does business or proposes to do business.

(c) The training and experience of the applicant in the transportation and care of patients.

(d) A description of each ambulance, including the make, model, year of manufacture, motor and chassis number; current state license number; the length of time the ambulance has been in use; and the color scheme, insignia, name, monogram or other distinguishing characteristics to be used to designate applicant's ambulance.

(e) The location and descriptions of the place or places from which it is intended to operate.

(f) Such other information as the License Officer shall deem reasonably necessary to a fair determination of compliance with this Ordinance.

(g) An accompanying license fee of $_____.

SECTION 4 **Standards for Ambulance License**

(a) Each ambulance shall, at all times when in use as such,

(i) conform with the standards, requirements and regulations provided for in this ordinance for the transportation of patients, from the standpoint of health, sanitation, and safety, and the nature of the premises in which it is maintained;

22817

(ii) contain equipment conforming with the standards, requirements and regulations provided for herein, which equipment shall be in proper and good condition for such use;

(iii) comply with all currently applicable laws and local ordinances relating to health, sanitation and safety; and

(iv) be equipped with such lights, sirens, and special markings to designate it as an ambulance as may be prescribed in reasonable regulations promulgated by the License Officer; and

(b) Any change of ownership of a licensed ambulance shall terminate the license and shall require a new application and a new license and conformance with all the requirements of this Ordinance as upon original licensing.

(c) Application for transfer of any ambulance license to another or substitute vehicle shall require conformance with all the requirements of this Ordinance as upon original licensing. No ambulance license may be sold, assigned, mortgaged, or otherwise transferred without the approval of the License Officer and a finding of conformance with all the requirements of this Ordinance as upon original licensing.

(d) Each licensed ambulance, its equipment and the premises designated in the application and all records relating to its maintenance and operation as such, shall be open to inspection by the License Officer or his designated representatives during usual hours of operation.

(e) No official entry made upon a license may be defaced, removed, or obliterated.

SECTION 5 **Standards for Ambulance License—Liability Insurance**

(a) No ambulance license shall be issued under this Ordinance, nor shall such license be valid after issuance, nor shall any ambulance be operated in (_____ _____city or county_____), unless there is at all times in force and effect insurance coverage, issued by an insurance company licensed to do business in the State of (_____), for each and every ambulance owned and/or operated by or for the applicant or licensee, providing

(i) for injury to or death of individuals in accidents resulting from any cause for which the owner of said ambulance would be liable on account of liability imposed on him by law, regardless of whether the ambulance was being driven by the owner or his agent, and

(ii) against damage to the property of another, including personal property, under like circumstances, in such sums and under such terms as may be required in regulations promulgated by the License Officer.

(b) Said insurance policies shall be submitted to the License Officer for approval prior to the issuance of each ambulance license. Satisfactory evidence that such insurance is at all times in force shall be furnished to the License Officer, in such form as he may specify, by all licensees required to provide such insurance under the provisions of this Ordinance.

(c) Every insurance policy required hereunder shall contain a provision for a continuing liability thereunder to the full amount thereof, notwithstanding any recovery thereon, that the liability of the insurer shall not be affected by the insolvency or the bankruptcy of the assured, and that until the policy is revoked the insurance company will not be relieved from liability on account of non-payment of premium, failure to renew license at the end of the year, or any act or omission of the named assured.

(d) Every insurance policy required hereunder shall extend for the period to be covered by the license applied for and the insurer shall be obliged to give net less than _____ days written notice to the License Officer and to the assured before any cancellation or termination of the policy earlier than its expiration date and the cancellation or other termination of any such

policy shall automatically revoke and terminate the licenses issued for the ambulances covered by such policy, unless another insurance policy complying with the provisions of this section shall be provided and be in effect at the time of such cancellation or termination.

SECTION 6 **Duties of License Officer**

(a) The License Officer shall, within _____ days after receipt of an application for an ambulance license as provided for herein, cause such investigation as he deems necessary to be made of the applicant and of his proposed operations.

(b) The License Officer shall issue a license hereunder for a specified ambulance, to be valid for a period of _____ years unless earlier suspended, revoked or terminated, when he finds that:

(i) the public convenience and necessity require the proposed ambulance service;

(ii) each such ambulance, its required equipment, and the premises designated in the application comply with the standards prescribed in Section 4(a) and in Sections 7 and 8 of this Ordinance and with the regulations promulgated under such sections;

(iii) the applicant is a responsible and proper person to conduct or work in the proposed business;

(iv) only duly licensed drivers, attendants, and attendant-drivers are employed in such capacities; and

(v) all the requirements of this Ordinance and all other applicable laws and ordinances have been met.

(c) Prior to the issuance of any ambulance license hereunder, the License Officer shall cause to be inspected the vehicles, equipment, and premises designated in each application hereunder, to determine compliance with the standards prescribed in Section 4(a) and in Sections 7 and 8 of this Ordinance and with the regulations promulgated under such sections.

(d) Subsequent to issuance of any ambulance license hereunder, the License Officer shall cause to be inspected each such licensed vehicle, and its equipment and premises, whenever he deems such inspection to be necessary but in any event no less frequently than twice each year. The periodic inspection required hereunder shall be in addition to any other safety or motor vehicle inspection required to be made for ambulances or other motor vehicles, or other inspections required to be made, under general law or ordinances, and shall not excuse compliance with any requirement of law or ordinance to display any official certificate of motor vehicle inspection and approval nor excuse compliance with the requirements of any other applicable general law or ordinance.

(e) A copy of each initial, semi-annual, or other ambulance, equipment, and premises inspection report by the License Officer under the provisions of this section shall be promptly transmitted to the applicant or licensee to whom it refers.

SECTION 7 **Standards for Ambulance Equipment—Duties of License Officer and Licensees**

(a) The License Officer shall promulgate standards for ambulance equipment under this Ordinance, and shall apply the standards certified by the Health Officer pursuant to the provisions of Section 8 of this Ordinance.

(b) Each licensee of an ambulance shall comply with such regulations as may be promulgated by the License Officer under the provisions of Section 7(a) and shall maintain in each such ambulance, at all times when it is in use as such, all such equipment as may be prescribed by the License Officer hereunder.

22819

SECTION 8 **Standards for Ambulance Equipment—Duties of Health Officer**

(a) Required equipment in each ambulance shall include, at all times when the ambulance is in use as such, equipment adequate in the judgment of the Health Officer for dressing wounds, splinting fractures, controlling hemorrhage, and providing oxygen.

(b) The Health Officer is authorized and directed, after public notice and opportunity for public hearing, to certify to the License Officer standards for ambulance equipment to implement the standards provided herein as to required equipment in ambulances. In determining the adequacy of equipment, the Health Officer shall take into consideration the current list of minimal equipment for ambulances, adopted by the American College of Surgeons or its duly authorized Committee on Trauma.

SECTION 9 **Applications for Drivers, Attendants and Attendant-Drivers License.**

Applications for drivers, attendants, and attendant-drivers licenses hereunder shall be made upon such forms as may be prepared or purchased by the License Officer and shall contain:

(a) The applicant's full name, current residence, places of residence for _____ years previous to moving to his present address, and length of time he has resided in (_____city or county_____).

(b) The applicant's age, marital status, height, and color of eyes and hair.

(c) Whether he has ever been convicted of a felony or misdemeanor, and if so, when and where and for what cause.

(d) The applicant's training and experience in the transportation and care of patients, and whether he has previously been licensed as a driver, chauffeur, attendant, or attendant-driver, and if so, when and where, and whether his license has ever been revoked or suspended in any jurisdiction and for what cause.

(e) Affidavits of good character from two reputable citizens of the United States and residents of (_____city or county_____) who have personally known such applicant and observed his conduct during _____ years next preceding the date of his application.

(f) Two recent photographs of the applicant, of a size designated by the License Officer, one of which shall be attached by the License Officer to the license.

(g) Such other information as the License Officer shall deem reasonably necessary to a fair determination of compliance with this Ordinance.

(h) An accompanying license fee or $_____.

SECTION 10 **Standards for Drivers, Attendants and Attendant-Drivers License**

(a) The License Officer shall, within a reasonable time after receipt of an application as provided for herein, cause such investigation as he deems necessary to be made of the applicant for a drivers, attendants, or attendant-drivers license.

(b) The License Officer shall issue a license to a driver, attendant or attendant-driver hereunder, valid for a period of _____ years, unless earlier suspended, revoked, or terminated, when he finds that:

(i) the applicant is not addicted to the use of intoxicating liquors or narcotics, and is morally fit for the position;

(ii) the applicant is able to speak, read and write the English language;

(iii) the applicant has been found by a duly licensed physician, upon examination attested to on a form provided by the Health Officer, to be of sound physique, possessing eyesight corrected to at least 20/40 in the better eye, and free of physical defects or diseases that might impair the ability to drive or attend an ambulance; and

22820

5. Tact and Patience - The investigator must obtain the bulk of his information from persons who are generally under no compelling obligation to give it to him and who have a reluctance to get involved. Witnesses may be difficult to locate and when found may be unable to give information without careful questioning.

6. The Ability to Employ Logic - The investigator must be able to gather his facts and assemble them in a logical manner to determine what happened and to arrive at the accident cause. He must be aware that, in some cases, a definite cause cannot be determined and he must then be able to determine possible or probable causes.

7. Stamina - Because of the necessity of beginning each accident investigation promptly and tracking down clues and examining evidence before they become stale or are destroyed, the accident investigator must be able to stay on the job for protracted periods.

Because of the size and nature of a fleet operation, it may be necessary, to send a terminal manager, dispatcher or other company employee to the scene of an accident pending the arrival of the safety man. Such employees should have the necessary knowledge to protect the company's interests by notifying the insurance carrier (if this has not already been done), by protecting the cargo or making arrangements for such protection, by helping the driver to gather the necessary information for his accident report and by listing witnesses and gathering such additional factual information as they can for necessary follow-up by the safety man.

It is possible that other company employees may encounter company equipment involved in accidents. If such employees are not authorized to carry on any investigative activity, they should confine themselves to notifying the nearest terminal of the accident, to carrying out such instructions as they may be given, and to helping the company driver at the accident scene, or by taking charge until the arrival of company personnel assigned the task.

HOW THE INVESTIGATION STARTS

In most cases the investigation of an accident begins after the accident is reported by the driver involved. This fact highlights the necessity of training drivers in proper conduct at the scene of an accident, and in accurately recording the basic information for accident reports required by company policy and the law.

In training drivers on their conduct at the scene of an accident, first consideration must be given to instruction on protecting the scene through the use of the appropriate emergency warning devices. Drivers must be trained in the importance of extreme courtesy in dealing with others involved in the accident, with bystanders, and with the owners of other property involved. Above all, drivers must be instructed not to give out more information than required: a) the name and address of the company; b) their own name and address; c) show their chauffeur's license on request. In no case, should the company driver, in any way, admit responsibility for the accident regardless of the circumstances.

Information to be recorded by the driver includes:

a) Date, time and place.
b) Road surface and condition, weather and light conditions.
c) Names and addresses of owners and drivers of other vehicles or property involved, and names and addresses of passengers or others involved, whether or not injured, and if injured, where taken.
d) Names and addresses of witnesses, and license numbers of first vehicles on the scene after the accident.
e) Company driver's statement of what happened and similar statement by other driver if obtainable.
f) Description of damage to all vehicles, cargo and other property and estimate of amount of damage.
g) Name, badge and organization of investigating police officers.

Additional information on the driver's conduct at the scene of an accident is contained in "Minimum Standards for Selection and Training of Personnel," "Truck Drivers Handbook," and "Truck Driver Training," publications of the Department of Safety, American Trucking Associations, Inc.

22831

In most cases, drivers report being in accidents by telephone to the nearest company terminal. To facilitate receiving such reports from drivers and to insure that accurate basic information about the accident is obtained, many companies use a special form, such as that shown in the Appendix, to record drivers' telephoned reports of accidents. This form, or a copy, can then be turned over to the accident investigator. A form of this type leaves nothing to chance, as it can be used by the person receiving the phone call to remind the driver of the steps he should take at the scene to get all the necessary information.

Occasionally, a safety representative may come upon the accident scene in which one of his company's vehicles is involved. In this case, necessary information can be secured and the investigation initiated without delay.

WHEN TO DO IT

The investigation of an accident should commence as promptly as possible after the occurrence to permit the gathering of pertinent facts before the details become obscured and to permit the examination of physical evidence before it is altered or destroyed.

INVESTIGATION CONFIDENTIAL

The investigation must be conducted to elicit the greatest amount of information which will be useful in the fleet's accident prevention activities without revealing to others information which could prove prejudicial to the fleet's interests in subsequent legal action. In particular, the fleet safety man should avoid discussing the results of an investigation with anyone other than officials of his own company or representatives of the fleet's insurance carrier. He should always keep in mind the likelihood that others whose interests may be contrary to those of the fleet, will be investigating the same accident.

Inquiries from the press must, therefore, be handled carefully. A definite policy on this matter should be worked out by fleet management and its insurance carrier. In any event, the investigator should obtain authority from the fleet management before making public statements concerning accidents under investigation.

The fleet investigator must be prepared to deal with newspaper reporters seeking information about an accident and/or the results of the investigation. In general terms, such inquiries from the press represent legitimate public concern in an accident of public consequence. Such inquiries should be handled forthrightly. However, it should be kept in mind that statements made to the press can be misconstrued. It is important that the fleet's side of the story be told, where possible, to avoid the condemnation which often results from news stories written by persons who do not have all the facts or a full understanding of them.

TANDARDS-1963-A

(iv) for each applicant for attendant or attendant-drivers license, that such applicant has a currently valid certificate evidencing successful completion of a course of training equivalent to the advanced course in first aid given by the American Red Cross or the United States Bureau of Mines.

PROVIDED HOWEVER, that no one shall be licensed as a driver or attendant-driver unless he holds a currently valid permit from the State of (_____ _____) to drive an ambulance.

(c) A license as driver, attendant or attendant-driver issued hereunder shall not be assignable or transferable.

(d) No official entry made upon a license may be defaced, removed, or obliterated.

SECTION 11 **Renewal of License.** Removal of any license hereunder, upon expiration for any reason or after revocation, shall require conformance with all the requirements of this Ordinance as upon original licensing.

SECTION 12 **Revocation of License**

(a) The License Officer may, and is hereby authorized to, suspend or revoke a license issued hereunder for failure of a licensee to comply and to maintain compliance with, or for his violation of, any applicable provisions, standards or requirements of this Ordinance, or of regulations promulgated hereunder; or of any other applicable laws or ordinances or regulations promulgated thereunder, but only after warning and such reasonable time for compliance as may be set by the License Officer. Within _____ days after a suspension, the licensee shall be afforded a hearing, after reasonable notice. The License Officer shall, within _____ days after conclusion of such hearing, issue a written decision (which shall include written findings) as to the suspension of said license. Such written decision shall be promptly transmitted to the licensee to whom it refers.

(b) The initial, semi-annual, or other ambulance, equipment, and premise inspection reports of the License Officer herein provided for shall be *prima facie* evidence of compliance or non-compliance with, or violation of, the provisions, standards and requirements provided herein, and of the regulations promulgated hereunder, for the licensing of ambulances.

(c) Upon suspension, revocation or termination of an ambulance license hereunder, operations as such shall cease with such ambulance and no person shall permit continued operation with such ambulance as such. Upon suspension, revocation or termination of a drivers, attendants or attendant-drivers license hereunder, such driver, attendant or attendant-driver shall cease to drive or attend an ambulance and no person shall employ or permit such individual to drive or attend an ambulance.

SECTION 13 **Reports**

(a) Each licensee of an ambulance hereunder shall maintain accurate records, upon such forms as may be provided or prescribed by, and containing such information as may be required by, the (_____designated official _____) of (_____city or county_____), concerning the transportation of each patient within (_____city or county _____), or from one place herein to another place within or beyond its limits. Such records shall be available for inspection by the (_____ designated official_____) at any reasonable time and copies thereof shall be filed by the licensee within _____ hours upon request of the (_____designated official_____).

(b) The provisions of subsection (a) of this section shall apply with equal force in case the patient shall die before being so transported in such ambulance or dies while being transported therein or at any time prior to the acceptance

22821

of the patient into the responsibility of the hospital or medical or other authority if the patient is still under the care or responsibility of the ambulance licensee.

SECTION 14 **Obedience to Traffic Laws, Ordinances and Regulations**

(a) The driver of an ambulance, when responding to an emergency call or while transporting a patient, may exercise the privileges set forth in this section, but subject to the conditions herein stated, and only when such driver has reasonable grounds to believe that an emergency in fact exists that requires the exercise of such privileges.

(b) Subject to the provisions of subsection (a) hereof, the driver or an ambulance may:

(i) park or stand, irrespective of the otherwise applicable provisions of law, ordinance, or regulation;

(ii) proceed past a red or stop signal or stop sign, but only after slowing down as may be necessary for safe operation;

(iii) exceed the maximum speed limits permitted by laws, ordinances, or regulation so long as he does not endanger life or property; and

(iv) disregard laws, ordinances, or regulations governing direction or movement or turning in specified directions.

(c) The exemptions herein granted shall apply only when such ambulance is making use of audible and visual signals meeting the requirements of law, ordinance, or regulation.

(d) The foregoing provisions shall not relieve the driver of an ambulance from the duty to drive with due regard for the safety of all persons, nor shall such provisions protect the driver from the consequences of his reckless disregard for the safety of others.

SECTION 15 **Penalties**

(a) Any person violating, or failing to comply with, the provisions of Section 2 (a) of this Ordinance and the applicable provisions hereof relating to the licensing of ambulances, shall be deemed guilty of a misdemeanor and upon conviction thereof shall be fined an amount not exceeding $_____ or imprisoned for a period not exceeding _____ days, or be both so fined and imprisoned, for each offense.

(b) Any person violating, or failing to comply with, any other provision of this Ordinance shall be deemed guilty of a misdemeanor and upon conviction thereof shall be fined an amount not exceeding $_____ or be imprisoned for a period not exceeding _____ days, or be both so fined and imprisoned, for each offense.

(c) Each day that any violation of, or failure to comply with, this Ordinance is committed or permitted to continue shall constitute a separate and distinct offense under this section and shall be punishable as such hereunder; *provided, however,* that the Court may, in appropriate cases, stay the cumulation of penalties.

SECTION 16 **Separability.** If any section, subsection, sentence, clause, phrase or portion of this Ordinance is for any reason held invalid or unconstitutional by any court of competent jurisdiction, such portion shall be deemed a separate, distinct, and independent provision and such holding shall not affect the validity of the remaining portions hereof.

SECTION 17 **Effective Date.** This Ordinance shall become effective on (_____ _____date_____).

22822

SECTION 18 **Ordinances Repealed.** All ordinances and parts of ordinances in conflict with the provisions of this Ordinance are hereby repealed as follows:

_____

_____

_____

_____

Adopted this _____ day of _____, 19____.

APPENDIX "C"

Specific Types of Emergencies

For a number of specific types of emergencies requiring immediate care by the ambulance attendant before moving the patient, the Pennsylvania Department of Health's publication, "Ambulance Attendant Training Pilot Project Report" (see Reference 2), cites three basic rules and labels them *important*. These are:

1. Don't panic
2. Reassure patient with a confident manner
3. *No siren or fast ride* in most all cases

The specific types of trauma to which these rules refer are as follows:

1. Uncontrolled hemorrhage
2. Respiratory failure or blockage (in which resuscitation is not totally effective)
3. Petroleum-base poisonings
4. Cardiac failure due to fibrillation (in which closed-chest heart compression is used en route but cannot stop the fibrillation)
5. Acute burns (2nd and 3rd degree over large part of body)
6. Full-term maternity cases involving complications of normal delivery

ABSTRACT - This manual is designed for the guidance of truck fleet safety personnel and other fleet employees who may be given responsibility for investigating accidents involving vehicles operated by the company. Major emphasis is on accident prevention through accident investigation. To this end the manual is designed to enable motor career management and fleet safety personnel to collect and analyze information about each accident so that corrective measures may be taken for more effective training of drivers, revision of operating policies and procedures, correction of deficiencies in the maintenance program, disciplinary action, and cooperation with appropriate authorities to eliminate or reduce hazards at accident sites. Accident report forms, a speed nomography, and a drag factor table are appended. (Author/GB)

INTRODUCTION

An accident investigation is a search for facts. It must not only determine what happened in each accident, but it must go deeper to find out why it happened. The facts must then be studied to determine what can be done about it. It means more than just collecting the bare essentials of information needed to fill out required accident reports. It demands inquiry into many areas of human behavior, vehicle design and characteristics, and the environment of the accident. It requires a skillful and persistent investigator who will get all the facts without prejudgement and without attempting to support preconceived notions.

This manual is designed for the guidance of truck fleet safety personnel and other fleet employees who may be given responsibility for investigating accidents involving vehicles operated by the company. Major emphasis is on accident prevention through accident investigation, and to this end the manual is designed to enable motor carrier management and fleet safety personnel to collect and analyze information about each accident so that corrective measures may be taken for more effective training of drivers; revision of operating policies and procedures; correction of deficiencies in the maintenance program; disciplinary action; cooperation with appropriate authorities to eliminate or reduce existing hazards at accident sites, and the elimination of other hazardous conditions which may be uncovered.

The results of investigations can be checked against the fleet's overall accident experience to determine accident prevention needs and to give effective direction to its safety efforts.

The accurate determination of accident liability is vitally important to management because of its effect on accident costs. Investigation to make such a determination requires special training and skills. In addition to the type of fact-finding outlined in this manual, liability investigation requires legal knowledge which can be applied to the facts uncovered. It also entails investigation into the activities of third parties to determine possible contributory negligence.

In fleets having some form of self-insurance, it is a common practice for safety representatives to investigate accidents for the dual purposes of finding the cause and determining the company's liability in each instance. For fleets having the more conventional forms of insurance coverage, it is the practice for the liability investigation to be made by the insurance carrier or an independent adjuster. In any event, it is essential that all available facts of every accident be uncovered and made a matter of record for the information of fleet management and for the guidance of the fleet safety director.

To avoid the possibility of jeopardizing the fleets' position in legal action arising out of involvement in an accident, there must be full understanding and the closest cooperation between fleet management, the safety director and the fleet's insurance carrier, and between the safety and insurance departments within the fleet.

THE INVESTIGATION

WHAT TO INVESTIGATE

Ideally, all accidents involving vehicles operated by the motor carrier should be investigated to determine their basic causes. In practice, limitations of time and manpower, the scope of the company's operations, or other factors, may preclude complete investigation of every accident. An investigation should be made of every accident sufficiently serious to require a report to the Department of Transportation and/or state regulatory authorities.

The following list is presented as a further guide to the type of accident that should be investigated to determine causation:

a) Accidents involving fatalities and/or personal injuries.
b) Accidents involving large property damage.
c) Accidents involving the transportation of explosives and other dangerous articles, particularly where the nature of the cargo contributed to the seriousness of the accident.
d) Accidents involving vehicles or loads of abnormal dimensions and/or weight.
e) Accidents involving unusual circumstances.

A series of accidents involving common factors or circumstances which would indicate a pattern should also signal the need for investigation. Such an accident pattern would include, but not be limited to:

a) Involvement of a single driver in several accidents, particularly when such accidents occur in a relatively short period of time or involve recurrent similar circumstances.
b) Accidents occurring in a particular locality.
c) Accidents involving particular types of cargo.
d) Accidents involving certain types or makes of vehicles or combinations.
e) Accidents having other factors in common: e.g. a particular type of accident.

WHO INVESTIGATES

Fleet management should designate personnel authorized to investigate accidents and arrange for necessary training along the lines set forth in this manual. All fleet safety representatives should be qualified in accident investigation and their services should be used for this purpose whenever possible because their specialized knowledge of all aspects of safety tends to insure a more careful, accurate and fruitful investigation.

In determining who shall investigate accidents, consideration must be given to the essential qualifications of a good investigator including such attributes as:

1. Initiative - The good investigator knows that he cannot do his job from behind a desk, and that he cannot work in a preconcieved conclusion. He must go to the accident scene and start from there.

2. Imagination - He must be able to visualize what is needed in making his investigation and he must be able to set up the lines of initial inquiry.

3. Inquisitiveness - The good investigator recognizes that his job is basically a search. He must be constantly on the lookout for clues and more clues which he must follow until each one is proven worthless or fruitfull

4. Attention to Detail - The smallest detail may point to the cause of an accident, and if overlooked, may prevent the investigator from finding the cause, or lead him to a false conclusion.

22830

BASIC INFORMATION

Basic information must be secured and recorded on each accident. Much of this information is identical to the items of information necessary to complete required accident reports for the motor carrier's records, for the insurance company, state and federal regulatory agencies, and motor vehicle and police departments. In the course of a full-fledged accident investigation, the basic information should be checked and rechecked for completeness and for such additional information as may be uncovered and for sources of helpful background information which can be used in determining underlying causes of the accident.

Basic information must cover:

I Time and location

a. Date and time of occurrence

b. The precise location of the accident described in such a manner as to permit a complete stranger to the area to find the scene without undue difficulty. Information on the location should include:

State and county of occurrence and city, town or community, if applicable.

Route or street.

Street address in built-up areas.

Street intersection or route junction.

Distance and direction from nearest community or junction of routes as shown on ordinary road maps. Also, distance and direction from numbered highway, bridge, utility pole or the like.

Distance and direction from other landmarks such as a farm, park, roadside business establishment in conjunction with distance and direction from nearest community or junction of routes.

II Parties Involved

a. Names and addresses of:

The owners, drivers and occupants of all vehicles involved. Other persons involved and whether or not they were injured. Owners of other property involved.

III Witnesses and Police Officers

a. Names and addresses of witnesses or first arrivals at the scene.

b. License numbers of the first vehicles arriving at the scene.

c. Name, badge and organization of investigating police officers or other officials.

IV Vehicles Involved

a. For the motor carrier's vehicle show: make, model, year of manufacture, serial number, company identification, current state license number, body type, type of cargo, and gross weight. (Separate identification should be made of each vehicle in a combination unit)

b. The information in (a), above, should be recorded for other involved vehicles operated by other motor carriers.

c. For each vehicle or combination operated by a motor carrier, the appropriate certificate or permit number issued by a federal or state regulatory agency should be shown.

22833

d. With respect to leased vehicles operated by motor carriers, the name and address of both lessor and lessee of each such vehicle should be recorded.

e. If a bus was involved, the information outlined in the foregoing sub-paragraphs should be recorded together with the number of passengers on board, a list of the passengers, and a diagram showing where each passenger was sitting or standing.

f. For passenger cars and other small vehicles; record make, year of manufacture, body type and current state license number.

V Fatalities, Injuries and Property Damage

a. Persons injured or killed

Name, address, sex and age of each person (approximate age if exact age not available).

Nature and extent of injuries, whether serious or minor.

Nature of treatment required - hospitalization, treated at hospital and released, given first aid at scene, treatment declined or victim said he would see own doctor.

Status of each person injured as of the date of the investigation report - i.e. discharged from hospital, still in hospital, under out-patient care, etc.

Clinical cause of death for each person killed, as well as the events in the accident which are established as a cause of death.

Date and place of death of each person killed.

Much of the foregoing information must be obtained from outside sources. Diplomacy must be exercised in contacting officials who are not necessarily obliged to give the information.

b. Property Damage

Description of damage sustained by each vehicle involved.

Description of damage to cargo.

Description of damage to other property.

Estimate of dollar value of damage to each vehicle, cargo and item of other property and total damage estimate.

Determination of causes of damage.

VI The Accident and The Accident Scene

a. The Accident

Chronological description of accident sequence of events including direction of travel of each vehicle to point of impact and from point of impact to final resting place.

Established, estimated or reported speed of vehicles involved.

Statements of the company's driver, drivers of other vehicles involved, other persons involved and witnesses.

b. The Accident Scene

One of the vital functions of the accident investigator is to visit the scene of the accident as soon as possible to determine the role played by physical features and traffic conditions in the cause of the accident. If at all possible, he should be accompanied to the scene by the company driver who was involved. This practice serves two purposes in the course of the investigation. It enables the investigator to question the driver about salient points of the accident on the spot and it may also serve to refresh the driver's memory of the events leading up to the accident, or about its occurrence, so that he may be able to furnish the investigator with additional information.

22834

The initial check at the scene must include the measurements of the following:

Width of traffic lanes.

Width of the highway, including separately the right of way, travelled part of highway, shoulders and clearance between parked vehicles, buildings, safety islands or other obstructions.

Length, width and depth of ditches adjacent to accident.

Length of straightaway or curve.

Point of impact with respect to center line or curb line or edge of pavement.

Skid marks.

Distance and direction vehicles travelled after impact.

Distances from point of accident to warning signs or traffic control devices, including height of such signs or warning devices above pavement, and their condition and location as to visibility.

Location of sight obstructions and height of such obstructions above pavement.

Distances at which drivers of vehicles may have had sight of each other approaching scene of accident, especially in intersection accidents.

Distance from pavement to fixed object struck.

Distance from point of collision to detached parts of damaged vehicles.

Photographs showing the overall accident scene, position of vehicles, skid marks, debris, damage to vehicles or other property, pertinent features of the surroundings and any other photographs which "tell a story" about the accident should be taken. Each photograph must be identified as to date and time, distance from object, position of camera and direction of view, the object photographed and the signature and address of the photographer.

Information on the Accident Scene must include:

Road and traffic conditions.

Light conditions including the presence or absence of artificial highway lighting.

c. Reading The Signs at the Scene

While it is important that the investigator visit the accident scene promptly before physical evidence is destroyed, it is also important that he know what types of evidence to look for and how to interpret what he finds:

1. Debris

Debris is useful in establishing the exact location of the impact. In conjunction with observation of the final resting place of the vehicle(s) involved, it may help to establish their relative speeds. For example, if two vehicles of the same size collide head-on at equal speeds, they will tend to rebound an approximately equal distance from the point of impact. If two vehicles collide head-on and one is larger, or was travelling faster than the other, the larger, and/or faster vehicle will tend to push the other backward from the point of impact.

In some cases, debris will tend to follow the paths of the vehicles after impact.

Mud and dirt knocked loose from the colliding vehicle affords the best indication of the point of impact.

Vehicle parts, or portions of the cargo are less useful because of their tendency to scatter.

Spilled liquids from the cargo; water, oil, grease, or battery acid; and blood

may also help to establish location of impact. Liquids characteristically leave a stream or trail of drops from the point of impact to final resting place where they form a puddle.

2. Pavement Marks

Skid marks are the most common and useful pavement marks to be observed and studied in accident investigation. Skid marks are essentially tire smears resulting from friction between the braked wheels and the pavement which is great enough to actually scrape rubber off the tires.

Skid marks indicate: (1) the direction of movement of the vehicles involved before and after impact; (2) the approximate speed of the vehicles through measurement of length of the marks; (3) whether or not the drivers involved applied their brakes.

Skid marks generally indicate that the driver has lost steering control due to the locked wheels which have no steering power. However, if a combination unit is involved, tractor drive wheels and trailer wheels may lock up and leave skid marks while the front wheels do not, thus leaving the driver able to steer to some degree.

Scratch marks may be made by stones or metal imbedded in tires. Gouge marks, which are generally heavier than scratch marks, may be made by parts of the vehicle.

Scuff marks made by the outside edges of the tires as the vehicle reached the limit of adhesion rounding a curve may be found. With a knowledge of the vehicle, the sharpness of the curve, the length of the scuff marks and the condition and type of pavement, an estimate of speed may be made.

On hot blacktop surfaces, skidding wheels may leave characteristic smears.

On a wet pavement, a skidding wheel leaves a squeegee mark from the wiping and drying action. This type of mark is apt to be quickly obliterated by traffic or continued precipitation and is of limited usefulness in investigation.

On a hard surface covered with dust or loose material, the sliding wheel displaces the loose material to leave erasure marks.

On loose snow or on other soft surfaces, ruts or furrows may be found. A furrow is a ploughed depression made by a sliding tire while a rut is made by a rolling tire.

3. Using Skidmarks to Estimate Speed

Charts for use in estimating speed from skid marks are available and such a chart developed by The Traffic Institute of Northwestern University is reproduced in the Appendix through the courtesy of the Institute. This chart shows the relationship between the length of the skidmark, the speed, and the drag factor of the surface on which the vehicle was operating.

This relationship can also be computed, by use of the formulas shown on the nomograph. In these formulas:

s = speed in miles per hour
d = slide-to-stop distance in feet
F = drag factor
f = grade

In using the nomograph, the drag factor must be determined so that it and the length of the skid marks will be known factors for use in estimating the speed. For maximum accuracy, drag factor should be determined by making a test skid with the vehicle(s) (or the same type of vehicle(s)) involved in the accident on the surface on which the accident occurred. It is seldom practicable for the fleet investigator to do this. He should obtain the drag factor from the table reproduced in the Appendix

through the courtesy of The Traffic Institute. In practice, it may be desirable for the investigator to estimate a range of speeds using the maximum and minimum drag factors for the type of road surface involved. It should be noted that two groups of drag factors are shown in the table for "Under 30 m.p.h." and "Over 30 m.p.h." The investigator should select the proper group depending on posted speed limits or known prevailing speeds at the scene of the accident. Any grade at the scene must also be taken into account. This is done by determining the slope as a decimal. For an upgrade, the slope is added to the drag factor and for a downgrade, it is subtracted.

To make a speed estimate with the nomograph, a straight line is drawn from the figure indicating the length of the skid-marks, to the figure indicating the drag factor. The estimated speed is the point at which this line crosses the speed column.

The following points must be kept in mind in attempting to estimate speed from skid-marks:

a) The actual speed of the vehicle is invariably higher than the speed estimated from its skid-marks because some deceleration takes place before skid-marks are made. The actual speed may be much higher. Skid-marks may end abruptly at the point of impact. The speed estimated from their length may be very low while the extent of damage clearly indicates a higher speed.

b) The estimate will be accurate only if all wheels lock up and leave skid-marks. Because of size, weight, brake adjustment, the number of wheels, and similar factors, it is rare for all wheels of a large truck or a combination to lock-up and leave skid-marks. Therefore it is extremely difficult to obtain an accurate speed estimate. Any estimates of speed made from skid-marks should be checked against other types of speed estimates. However, it may prove valuable for the fleet investigator to measure skid-marks and estimate speeds for other vehicles involved.

c) Skid-marks must be identified with the vehicles involved in the accident. This can be a problem for the fleet investigator who may arrive at the scene some time after the accident and after the vehicles have been removed. He will need the assistance of the company driver who was involved or the help of someone else who can identify the skid-marks made by each vehicle. At some locations, identification of skid-marks made in a particular accident may be further complicated by the presence of skid-marks from prior or subsequent accidents or sudden stops.

d) It is essential to make separate measurements of the skid-marks left by each wheel and to record them, not only as to length, but also as to their position with respect to the edge or center-line of the roadway. Skid-marks made by duals are considered in the same manner as marks made by single-tire wheels.

e) It is necessary to identify the marks made by each wheel. On passenger cars, the marks made by the front wheels show on the pavement as twin streaks made predominantly by the outside edges of the front tires. This type of mark results from overloading of the front tires due to weight transfer resulting from the severe brake application. Rear tire marks of a passenger car are heavy ones made by the center of the tires which are underloaded due to the weight transfer caused by severe braking. Because of longer wheelbase and higher tire pressure, these phenomena do not occur with trucks and front and rear skid-marks are most easily identified by whether they show single-tire or dual-tire marks.

f) Be sure to measure the entire length of each skid-mark. Skid-marks are generally preceded by "shadow" or erasure marks made as the wheel begins to slide. However, these preliminary marks may be obliterated by the time the fleet investigator reaches the scene. If skid-marks of front and rear wheels overlap, it is necessary to subtract the wheelbase of the vehicle to determine the distance through which the vehicle slid.

g) It is essential to distinguish between skid-marks and tire prints. Tire prints are created by a rolling tire and show a complete tread

patterns. They show the path of a vehicle and are of no value in estimating speed. Tire prints at the scene of an accident are frequently made by passing vehicles which are not involved in the accident.

b) Gaps in skid-marks may or may not be included in measuring the length of the marks to estimate speed. Gap-skids indicating release of the brakes may be present and the length of the gaps must be deducted from the overall length of the skid-marks before attempting to estimate speed. On the other hand, the bouncing of braked wheels, such as the wheel-hop of a tandem axle assembly, will leave skip-skids at short intervals. Skip-skids must be included in measuring the overall length of the skid-marks to estimate speed.

DEVELOPING BACKGROUND INFORMATION

The collection of basic information about an accident in sufficient detail to permit the preparation of required accident reports may also permit an analysis of the accident which will reveal the cause and indicate necessary corrective measures. In many cases, however, it will be necessary for the fleet investigator to probe more deeply in order to uncover the basic causes. Such additional investigation may be made in one or more of four general areas: the driver; the trip; the vehicle; the environment. In making such further investigations, the fleet safety man must remember that he has direct authority and access to records and information only within his own company. Other information can generally be obtained only with the cooperation of other persons or agencies.

Whenever any given line of inquiry is found to reveal no significant information relative to the cause of an accident, it should be discontinued. At the same time, the investigator must be aware that the causes of accidents are not apparent; a lines of investigation will have to be followed in arriving at the causes of some accidents. In some cases, it will be necessary to analyze a great many contributing factors to determine both the immediate and underlying causes of a particular accident. Every conceivable line of investigation is pertinent to every accident, none should be disregarded until proven irrelevant.

During the investigation, the fleet safety man must work closely with the representatives of the insurance carrier, or, in the case of a self-insured fleet, with the company's claims representative. This cooperation must exist to avoid the possibility of jeopardizing the company's position in subsequent legal action, and also, to enable the safety man to receive information which he might not otherwise get. Reciprocally, the safety man should transmit the results of his investigation to the insurance carrier or the company's claims representatives for their use.

THE DRIVERS INVOLVED

Because the vast majority of accidents arise out of the improper actions of one or more drivers, it is desirable to gather as much information as possible about each driver involved in the accident under investigation. Information about the company's driver should be readily available from the fleet's personnel records. Comparable information about other drivers or about pedestrians or passengers in other vehicles is likely to be more difficult to secure. In some cases, depending upon state laws, information about accident and arrest records of other drivers may be obtained from the police or the state motor vehicle agency.

The following list of items to be investigated is specifically applicable to the company's driver, and should be readily obtainable from the fleet's personnel records.

a) Length of employment
b) Previous employment
c) Information from personal references
d) Training
e) Overall driving experience and experience driving type of vehicle involved in accident.
f) Attitude toward job
g) Record of physical examinations
h) Accident record
i) Record of complaints, especially those dealing with safety of operations, and record of warnings and convictions for traffic violations.
j) Commendations
k) Disciplinary actions
l) Illness and personal problems
m) General reputation

n) Physical and mental condition at time of accident.

Factors applicable to other drivers involved such as driving experience, accident and arrest record, physical and mental condition, and general reputation may shed light on the cause of an accident. They should be investigated as thoroughly as possible where they appear to be of significance.

THE TRIP

a) Show the origin, destination and related distances of the trip on which the accident occurred. If the total trip extends over more than one day, the point at which driving began on the day of the accident should be shown, as well as the origin and destination of the entire trip.
b) Show distance covered from point of origin to accident scene.
c) List stops enroute, time spent at each and reconstruction of the driver's activities at each stop.
d) Reconstruct driver's activities for at least 24 hours prior to the accident showing time spent on and off-duty and endeavor to find how driver spent his off-duty time. Investigate driver's activities over a longer period of time preceding the accident double-checked where it appears desirable. A copy of the driver's log record for the same period should be made a part of the company's accident file and record. If the vehicle was equipped with an opertiosu recorder, the chart should be reexamined with special attention to speed and stops enroute, and its correlation with the drivers log. This chart, or a facsimile, should be a permanent part of the accident file.

Insofar as possible, the activities of other drivers, or other persons involved, should be reconstructed in the effort to determine the extent to which their actions or their physical and mental condition may have contributed to the accident. Such investigation should also cover a period of at least 24 hours prior to the accident and a longer period, if such appears fruitful. Information relative to the activities of other persons will generally have to be developed through direct inquiry.

THE ENVIRONMENT
